# 1 Analysis

One of the topics in the A Level Further Maths course is linear transformations, as represented by matrices. This is a topic all about how vectors move and get transformed in the plane. It's a topic that lends itself exceedingly well to visualization, but students often find it hard to visualize this themselves, and there is a considerable lack of good tools to provide visual intuition on the subject. There is the YouTube series *Essence of Linear Algebra* by 3blue1brown[7], which is excellent, but I couldn't find any good interactive visualizations.

My solution is to develop a desktop application that will allow the user to define  $2 \times 2$  matrices and view these matrices and compositions thereof as linear transformations of a 2D plane. This will give students a way to get to grips with linear transformations in a more hands-on way, and will give teachers the ability to easily and visually show concepts like the determinant and invariant lines.

## 1.1 Computational Approach

This solution is particularly well suited to a computational approach since it is entirely focussed on visualizing transformations, which require complex mathematics to properly display. It will also have lots of settings to allow the user to configure aspects of the visualization. As previously mentioned, visualizing transformations in one's own head is difficult, so a piece of software to do it would be very valuable to teachers and learners, but current solutions are considerably lacking.

My solution will make use of abstraction by allowing the user to define a set of matrices which they can use in expressions. This allows them to use a matrix multiple times and they don't have to keep track of any of the numbers. All the actual processing and mathematics happens behind the scenes and the user never has to worry about it - they just compose their defined matrices into transformations. This abstraction allows the user to focus on exploring the transformations themselves without having to do any actual computations. This will make learning the subject much easier, as they will be able to gain a visual intuition for linear transformations without worrying about computation until after they've built up that intuition.

I will also employ decomposition and modularization by breaking the project down into many smaller parts, such as one module to keep track of defined matrices, one module to validate and parse matrix expressions, one module for the main GUI, as well as sub-modules for the widgets and dialog boxes, etc. This decomposition allows for simpler project design, easier code maintenance (since module coupling is kept to a minimum, so bugs are isolated in their modules), inheritance of classes to reduce code repetition, and unit testing to inform development. I also intend this unit testing to be automated using GitHub Actions.

Selection will also be used widely in the application. The GUI will provide many settings for visualization, and these settings will need to be checked when rendering the transformation. For example, the user will have the option to render the determinant, so I will need to check this setting on every render cycle and only render the determinant parallelogram if the user has enabled that option. The app will have many options for visualization, which will be useful in learning, but if all these options were being rendered at the same time, then there would be too much information for the user to properly process, so I will let the user configure these display options to their liking and only render the things they want to be rendered.

Validation will also be prevalent because the matrix expressions will need to follow a strict format, which will be validated. The buttons to render and animate the matrix will only be clickable when the given expression is valid, so I will need to check this and update the buttons every time the text in the text box is changed. I will also need to parse matrix expressions so that I can evaluate them properly. All this validation ensures that crashes due to malformed input are practically impossible, and makes the user's life easier since they don't need to worry about if their input is in the right format - the app will tell them.

I will also make use of iteration, primarily in animation. I will have to re-calculate positions and

values to render everything for every frame of the animation and this will likely be done with a simple `for` loop. A `for` loop will allow me to just loop over every frame and use the counter variable as a way to measure how far through the animation we are on each frame. This is preferable to a `while` loop, since that would require me to keep track of which frame we're on with a separate variable.

Finally, the core of the application is visualization, so that will definitely be used a lot. I will have to calculate positions of points and lines based on given matrices, and when animating, I will also have to calculate these matrices based on the current frame. Then I will have to use the rendering capabilities of the GUI framework that I choose to render these calculated points and lines onto a widget, which will form the viewport of the main GUI. I may also have to convert between coordinate systems. I will have the origin in the middle with positive  $x$  going to the right and positive  $y$  going up, but I may need to convert that to standard computer graphics coordinates with the origin in the top left, positive  $x$  going to the right, and positive  $y$  going down. This visualization of linear transformations is the core component of the app and is the primary feature, so it is incredibly important.

## 1.2 Stakeholders

Stakeholders for my app include A Level Further Maths students and teachers, who learn and teach linear transformations respectively. They will be able to provide useful input as to what they would like to see in the app, and they can provide feedback on what they like and what I can add or improve. I already know from experience that linear transformations are tricky to visualize and a computer-based visualization would be useful. My stakeholders agreed with this. Many teachers said that a desktop app that could render and animate linear transformations would be useful in a classroom environment and students said that it would be helpful to have something that they could play around with at home and use to get to grips with matrices and linear transformations.

Some teachers also suggested that it would be useful to have an option to save and load sets of matrices. This would allow them to have a single save file containing some matrices, and then just load this file to use for demonstrations in the classroom. This would probably be quite easy to implement. I could just wrap all the relevant information into one object and use Python's `pickle` module to save the binary data to a file, and then load this data back into the app in a similar way.

My stakeholders agreed that being able to see incremental animation - where, for example, we apply matrix **A** to the current scene, pause, and then apply matrix **B** - would be beneficial. This would be a good demonstration of matrix multiplication being non-commutative. **AB** is not always equal to **BA**. Being able to see this in terms of animating linear transformations would be good for learning.

They also agreed that a tutorial on using the software would be useful, so I plan to implement this through an online written tutorial hosted with GitHub Pages, and perhaps a video tutorial as well. This would make the app much easier to use for people who have never seen it before. It wouldn't be a lesson on the maths itself, just a guide on how to use the software.

## 1.3 Research on existing solutions

There are actually quite a few web apps designed to help visualize 2D linear transformations but many of them are hard to use and lacking many features.

### 1.3.1 MIT 'Matrix Vector' Mathlet

Arguably the best app that I found was an MIT 'Mathlet' - a simple web app designed to help visualize a maths concept. This one is called 'Matrix Vector'[8] and allows the user to drag an input vector around the plane and see the corresponding output vector, transformed by a matrix that the user can define, although this definition is finicky since it involves sliders rather than keyboard input.

This app fails in two crucial ways in my opinion. It doesn't show the basis vectors or let the user drag them around, and the user can only define and therefore visualize a single matrix at once. This second problem was common among every solution I found, so I won't mention it again, but it is a big issue in my opinion and my app will allow for multiple matrices. I like the idea of having a draggable input vector and rendering its output, so I will probably have this feature in my app, but I also want the ability to define multiple matrices and be able to drag the basis vectors to visually define a matrix. Being able to drag the basis vectors will help build intuition, so I think this would greatly benefit the app.

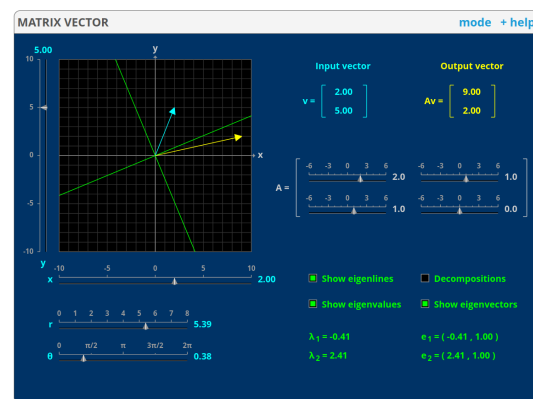

Figure 1.1: The MIT 'Matrix Vector' Mathlet

However, in the comments on this Mathlet, a user called 'David S. Bruce' suggested that the Mathlet should display the basis vectors, to which a user called 'hrm' (who I assume to be the 'H. Miller' to whom the copyright of the whole website is accredited) replied saying that this Mathlet is primarily focussed on eigenvectors, that it is perhaps badly named, and that displaying the basis vectors 'would make a good focus for a second Mathlet about  $2 \times 2$  matrices'. This Mathlet does not exist. But I do like the idea of showing the eigenvectors and eigenlines, so I will definitely have that in my app. Showing the invariant lines or lack thereof will help with learning, since these are often hard to visualize.

### 1.3.2 Linear Transformation Visualizer

Figure 1.2: 'Linear Transformation Visualizer' halfway through an animation

Another web app that I found was one simply called 'Linear Transformation Visualizer' by Shad Sharma[22]. This one was similarly inspired by 3blue1brown's YouTube series. This app has the ability to render input and output vectors and eigenlines, but it can also render the determinant parallelogram; it allows the user to drag the basis vectors; and it has the option to snap vectors to the background grid, which is quite useful. It also implements a simple form of animation where the tips of the vectors move in straight lines from where they start to where they end, and the animation is controlled by dragging a slider labelled  $t$ . This isn't particularly intuitive.

I really like the vectors snapping to the grid, the input and output vectors, and rendering the determinant. This app also renders positive and negative determinants in different colours, which is really nice - I intend to use that idea in my own app, since it helps create understanding about negative determinants in terms of orientation changes. However, I think that the animation system here is flawed and not very easy to use. My animation will likely be a button, which just triggers an animation, rather than a slider. I also don't like the way vector dragging is handled. If you click anywhere on the grid, then the closest vector target (the final position of the target's associated vector) snaps to that location. I think it would be more intuitive to have to drag the vector from its current location to where you want it. This was also a problem with the MIT Mathlet.

### 1.3.3 Desmos app

One of the solutions I found was a Desmos app[6], which was quite hard to use and arguably over-complicated. Desmos is not designed for this kind of thing - it's designed to graph pure mathematical functions - and it shows here. However, this app brings some really interesting ideas to the table, mainly functions. This app allows you to define custom functions and view them before and after the transformation. This is achieved by treating the functions parametrically as the set of points  $(t, f(t))$  and then transforming each coordinate by the given matrix to get a new coordinate.

Figure 1.3: The Desmos app halfway through an animation, rendering  $f(x) = \frac{\sin^2 x}{x}$  in orange

Desmos does this for every point and then renders the resulting transformed function parametrically. This is a really interesting technique and idea, but I'm not going to use it in my app. I don't think arbitrary functions fit with the linearity of the whole app, and I don't think it's necessary. It's just overcomplicating things, and rendering it on a widget would be tricky, because I'd have to render every point myself, possibly using something like OpenGL. It's just not worth implementing.

Additionally, this Desmos app makes things quite hard to see. It's hard to tell where any of the vectors are - they just get lost in the sea of grid lines. This image also hides some of the extra information. For instance, this image doesn't show the original function  $f(x) = \frac{\sin^2 x}{x}$ , only the transformed version. This app easily gets quite cluttered. I will give my vectors arrowheads to make them easily identifiable amongst the grid lines.

### 1.3.4 Visualizing Linear Transformations

Figure 1.4: The GeoGebra applet rendering its default matrix

The last solution that I want to talk about is a GeoGebra applet simply titled 'Visualizing Linear Transformations'[10]. This applet has input and output vectors, original and transformed grid lines, a unit circle, and the letter N. It allows the user to define a matrix as 4 numbers and view the aforementioned N (which the user can translate to anywhere on the grid), the unit circle, the input/output vectors, and the grid lines. It also has the input vector snapping to integer coordinates, but that's a standard part of GeoGebra.

I've already talked about most of these features but the thing I wanted to talk about here is the N. I don't particularly want the letter N to be a prominent part of my own app, but I really like the idea of being able to define a custom polygon and see how that polygon gets transformed by a given transformation. I think that would really help with building intuition and it shouldn't be too hard to implement.

## 1.4 Essential features

The primary aim of this application is to visualize linear transformations, so this will obviously be the centre of the app and an essential feature. I will have a widget which can render a background grid and a second version of the grid, transformed according to a user-defined matrix expression. This is necessary because it is the entire purpose of the app. It's designed to visualize linear transformations and would be completely useless without this visual component. I will give the user the ability to render a custom matrix expression containing matrices they have previously defined, as well as reset the canvas to the default identity matrix transformation. This will obviously require an input box to enter the expression, a render button, a reset button, and various dialog boxes to define matrices in different ways. I want the user to be able to define a matrix as a set of 4 numbers, and by dragging the basis vectors  $i$  and  $j$ . These dialogs will allow the user to define new matrices to be used in expressions, and having multiple ways to do it will make it easier, and will aid learning.

Another essential feature is animation. I want the user to be able to smoothly animate between matrices. I see two options for how this could work. If  $\mathbf{C}$  is the matrix for the currently displayed transformation, and  $\mathbf{T}$  is the matrix for the target transformation, then we could either animate from  $\mathbf{C}$  to  $\mathbf{T}$  or we could animate from  $\mathbf{C}$  to  $\mathbf{TC}$ . I would probably call these transitional and applicative animation respectively. Perhaps I'll give the user the option to choose which animation method they want to use. Either way, animation is used in most of the alternative solutions that I found, and it's a great way to build intuition, by allowing students to watch the transformation happen in real time. Compared to simply rendering the transformations, animating them would profoundly benefit learning, and since that's the main aim of the project, I think animation is a necessary part of the app.

Something that I thought was a big problem in every alternative solution I found was the fact that the user could only visualize a single matrix at once. I see this as a fatal flaw and I will allow the user to define 25 different matrices (all capital letters except  $\mathbf{I}$  for the identity matrix) and use all of them in expressions. This will allow teachers to define multiple matrices and then just change the expression to demonstrate different concepts rather than redefine a new transformation every time. It will also make things easier for students as it will allow them to visualize compositions of different matrix transformations without having to do any computations themselves.

Additionally, being able to show information on the currently displayed matrix is an essential tool for learning. Rendering things like the determinant parallelogram and the invariant lines of the transformation will greatly assist with learning and building understanding, so I think that having the option to render these attributes of the currently displayed transformation is necessary for success.

## 1.5 Limitations

The main limitation in this app is likely to be drawing grid lines. Most transformations will be fine but in some cases, the app will be required to draw potentially thousands of grid lines on the canvas and this will probably cause noticeable lag, especially in the animations. I will have to artificially limit the number of grid lines that can be drawn on the screen. This won't look fantastic, because it means that the grid lines will only extend a certain distance from the origin, but it's an inherent limitation of computers. Perhaps if I was using a faster, compiled language like C++ rather than Python, this processing would happen faster and I could render more grid lines, but it's impossible to render all the grid lines and any implementation of this idea must limit them for performance.

An interesting limitation is that I don't think I'll implement panning. I suspect that I'll have to convert between coordinate systems and having the origin in the centre of the canvas will probably make the code much simpler. Also, linear transformations always leave the origin fixed, so always having it in the centre of the canvas seems thematically appropriate. Panning is certainly an option - the Desmos solution in §1.3.3 and GeoGebra solution in §1.3.4 both allow panning as a default part of Desmos and GeoGebra respectively, for example - but I don't think I'll implement it myself. I just don't think it's worth it.

I'm also not going to do any work with 3D linear transformations. 3D transformations are often harder to visualize and thus it would make sense to target them in an app like this, designed to help with learning and intuition, but 3D transformations are also harder to code. I would have to use a full graphics package rather than a simple widget, and I think it would be too much work for this project and I wouldn't be able to do it in the time frame. It's definitely a good idea, but I'm currently incapable of creating an app like that.

There are other limitations inherent to matrices. For instance, it's impossible to take an inverse of a singular matrix. There's nothing I can do about that without rewriting most of mathematics. Matrices can also only represent linear transformations. There's definitely a market for an app that could render any arbitrary transformation from  $\mathbb{R}^2 \rightarrow \mathbb{R}^2$  - I know I'd want an app like that - but matrices can only represent linear transformations, so those are the only kind of transformations that I'll be looking at with this project.

## 1.6 Hardware and software requirements

### 1.6.1 Hardware

Hardware requirements for the project are the same between the release and development environments and they're quite simple. I expect the app to require a processor with at least 1 GHz clock speed, \$BINARY\_SIZE free disk space, and about 1 GB of available RAM. The processor and RAM requirements are needed by the Python runtime and mainly by Qt5 - the GUI library I'll be using. The \$BINARY\_SIZE disk space is just for the executable binary that I'll compile for the public release. The code itself is less than 1 MB, but the compiled binary has to package all the dependencies and the entire CPython runtime to allow it to run on systems that don't have that, so the file size is much bigger.

I will also require that the user has a monitor that is at least  $1920 \times 1080$  pixels in resolution. This isn't necessarily required, because the app will likely run in a smaller window, but a HD monitor is highly recommended. This allows the user to go fullscreen if they want to, and it gives them enough resolution to easily see everything in the app. A large, wall-mounted screen is also highly recommended for use in the classroom, although this is common among schools.

I will also require a keyboard with all standard Latin alphabet characters. This is because the matrices are defined as uppercase Latin letters. Any UK or US keyboard will suffice for this. The app will also require a mouse with at least one button. I don't intend to have right click do anything, so only the primary mouse button is required, although getting a single button mouse to actually work on modern computers is probably quite a challenge. A separate mouse is not strictly required - a laptop trackpad is equally sufficient.

### 1.6.2 Software

Software requirements differ slightly between release and development, although everything that the release environment requires is also required by the development environment. I will require a modern operating system - namely Windows 10 or later, macOS 10.9 'Mavericks'<sup>1</sup> or later, or any modern Linux distro<sup>2</sup>. Basically, it just requires an operating system that is compatible with Python 3.10 and Qt5, since I'll be using these in the project. Of course, Qt5 will need to be installed on the user's computer, although it's standard pretty much everywhere these days.

Python 3.10 won't actually be required for the end user, because I will be compiling the app into a stand-alone binary executable for release, and this binary will contain the required Python runtime and dependencies. However, if the user wishes to download and run the source code themselves, then

---

<sup>1</sup>Python 3.10 won't compile on any earlier versions of macOS[16]

<sup>2</sup>Specifying a Linux version is practically impossible. Python 3.10 isn't available in many package repositories, but will compile on any modern distro. Qt5 is available in many package repositories and can be compiled on any x86 or x86\_64 generic Linux machine with gcc version 5 or later[17]

they will need Python 3.10 and the package dependencies: `numpy`, `nptyping`, and `pyqt5`. These can be automatically installed with the command `python -m pip install -r requirements.txt` from the root of the repository. `numpy` is a maths library that allows for fast matrix maths; `nptyping` is used by `mypy` for type-checking and isn't actually a runtime dependency but the imports in the `typing` module fail if it's not installed at runtime; and `pyqt5` is a library that just allows interop between Python and Qt5, which is originally a C++ library.

In the development environment, I use PyCharm for actually writing my code, and I use a virtual environment to isolate my project dependencies. There are also some development dependencies listed in the file `dev_requirements.txt`. They are: `mypy`, `pyqt5-stubs`, `flake8`, `pycodestyle`, `pydocstyle`, and `pytest`. `mypy` is a static type checker<sup>3</sup>; `pyqt5-stubs` is a collection of type annotations for the PyQt5 API for `mypy` to use; `flake8`, `pycodestyle`, and `pydocstyle` are all linters; and `pytest` is a unit testing framework. I use these libraries to make sure my code is good quality and actually working properly during development.

## 1.7 Success criteria

The main aim of the app is to help teach students about linear transformations. As such, the primary measure of success will be letting teachers get to grips with the app and then asking if they would use it in the classroom or recommend it to students to use at home.

Additionally, the app must fulfil some basic requirements:

1. It must allow the user to define multiple matrices in at least two different ways (numerically and visually)
2. It must be able to validate arbitrary matrix expressions
3. It must be able to render any valid matrix expression
4. It must be able to animate any valid matrix expression
5. It must be able to display information about the currently rendered transformation (determinant, eigenlines, etc.)
6. It must be able to save and load sessions (defined matrices, display settings, etc.)
7. It must allow the user to define and transform arbitrary polygons

Defining multiple matrices is a feature that I thought was lacking from every other solution I researched, and I think it would make the app much easier to use, so I think it's necessary for success. Validating matrix expressions is necessary because if the user tries to render an expression that doesn't make sense, has an undefined matrix, or contains the inverse of a singular matrix, then we have to disallow that or else the app will crash.

Visualizing matrix expressions as linear transformations is the core part of the app, so basic rendering of them is definitely a requirement for success. Animating these expressions is also a pretty crucial part of the app, so I would consider this necessary for success. Displaying the information of a matrix transformation is also very useful for building understanding, so I would consider this needed to succeed.

Saving and loading isn't strictly necessary for success, but it is a standard part of many apps, so will likely be expected by users, and it will benefit the app by allowing teachers to plan lessons in advance and save the matrices they've defined for that lesson to be loaded later.

Transforming polygons is the lowest priority item on this list and will likely be implemented last, but it would definitely benefit learning. I wouldn't consider it necessary for success, but it would be very good to include, and it's certainly a feature that I want to have.

---

<sup>3</sup>Python has weak, dynamic typing with optional type annotations but `mypy` enforces these static type annotations

If the majority of teachers would use and/or recommend the app and it meets all of these points, then I will consider the app as a whole to be a success.

## 2 Design

### 2.1 Problem decomposition

I have decomposed the problem of visualization as follows:

Defining matrices is key to visualization because we need to have matrices to actually visualize. This is a key part of the app, and the user will be able to define multiple separate matrices numerically and visually using the GUI.

Evaluating expressions is another key part of the app and can be further broken down into validating, parsing, and computing the value. Validating an expression simply consists of checking that it adheres to a set of syntax rules for matrix expressions, and that it only contains matrices which have already been defined. Parsing consists of breaking an expression down into tokens, which are then much easier to evaluate. Computing the expression with these tokens is then just a series of simple operations, which will produce a final matrix at the end.

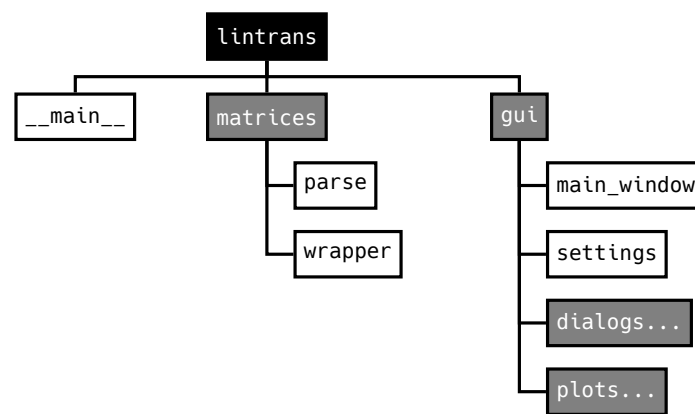

Rendering and animating will likely be the largest part in reality, but I've only decomposed it into simple blocks here. Evaluating positions involves evaluating the matrix expression that the user has input and using the columns of the resultant matrix to find the new positions of the basis vectors, and then extrapolating this for the rest of the plane. Rendering onto the widget is likely to be quite complicated and framework-dependent, so I've abstracted away the details for brevity here. Rendering will involve using the previously calculated values to render grid lines and vectors. Animating will probably be a `for` loop which just renders slightly different matrices onto the widget and sleeps momentarily between frames.

I have deliberately broken this problem down into parts that can be easily translated into modules in my eventual coded solution. This is simply to ease the design and development process, since now I already know my basic project structure. This problem could've been broken down into the parts that the user will directly interact with, but that would be less useful to me when actually starting development, since I would then have to decompose the problem differently to write the actual code.

### 2.2 Structure of the solution

#### 2.2.1 The main project

I have decomposed my solution like so:

The `lintrans` node is simply the root of the whole project. `__main__` is the Python way to make the project executable as `python -m lintrans` on the command line. For release, I will package it into a standalone binary executable.

`matrices` is the package that will allow the user to define, validate, parse, evaluate, and use matrices. The `parse` module will contain functions to validate matrix expressions - likely using regular expressions - and functions to parse matrix expressions. It will not know which matrices are defined, so validation will be naïve and evaluation will be elsewhere. The `wrapper` module will contain a `MatrixWrapper` class, which will hold a dictionary of matrix names and values. It is this class which will have aware validation - making sure that all matrices are actually defined - as well the ability to evaluate matrix expressions, in addition to its basic behaviour of setting and getting matrices. This `matrices` package will also have a `create_rotation_matrix` function that will generate a rotation matrix from an angle using the formula  $\begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}$ . It will be in the `wrapper` module since it's related to defining and manipulating matrices, but it will be exported and accessible as `lintrans.matrices.create_rotation_matrix`.

`gui` is the package that will contain all the frontend code for everything GUI-related. `main_window` is the module that will contain a `LintransMainWindow` class, which will act as the main window of the application and have an instance of `MatrixWrapper` to keep track of which matrices are defined and allow for evaluation of matrix expressions. It will also have methods for rendering and animating matrix expressions, which will be connected to buttons in the GUI. This module will also contain a simple `main()` function to instantiate and launch the application GUI.

The `settings` module will contain a `DisplaySettings` dataclass<sup>4</sup> that will represent the settings for visualizing transformations. The `LintransMainWindow` class will have an instance of this class and check against it when rendering things. The user will be able to open a dialog to change these display settings, which will update the main window's instance of this class.

The `settings` module will also have a `GlobalSettings` class, which will represent the global settings for the application, such as the logging level, where to save the logs, whether to ask the user if they want to be prompted with a tutorial whenever they open the app, etc. This class will have defaults for everything, but the constructor will try to read these settings from a config file if possible. This allows for persistent settings between sessions. This config file will be `~/.config/lintrans.conf` on Unix-like systems, including macOS, and `C:\Users\%USER%\AppData\Roaming\lintrans\config.txt` on Windows. This difference is to remain consistent with operating system conventions<sup>5</sup>.

<sup>4</sup>This is the Python equivalent of a `struct` or `record` in other languages

<sup>5</sup>And also to avoid confusing Windows users with a `.conf` file

### 2.2.2 The gui subpackages

The `dialogs` subpackage will contain modules with different dialog classes. It will have a `define_new_matrices` module, which will have a `DefinedDialog` abstract superclass. It will also contain classes that inherit from this superclass and provide dialogs for defining new matrices visually, numerically, and as an expression in terms of other matrices. Additionally, this subpackage will contain a `settings` module, which will provide a `SettingsDialog` superclass and a `DisplaySettingsDialog` class, which will allow the user to configure the aforementioned display settings. It will also have a `GlobalSettingsDialog` class, which will similarly allow the user to configure the app's global settings through a dialog.

The `plots` subpackage will have a `classes` module and a `widgets` module. The `classes` module will have the abstract superclasses `BackgroundPlot` and `VectorGridPlot`. The former will provide helper methods to convert between coordinate systems and draw the background grid, while the latter will provide helper methods to draw transformations and their components. It will have `point_i` and `point_j` attributes and will provide methods to draw the transformed version of the grid, the vectors and their arrowheads, the eigenlines of the transformation, etc. These methods can then be called from the Qt5 `paintEvent` handler which will be declared abstract and must therefore be implemented by all subclasses.

The `plots` subpackage will also contain a `widgets` module, which will have the classes `VisualizeTransformationWidget` and `DefineVisuallyWidget`, both of which will inherit from `VectorGridPlot`. They will both implement their own `paintEvent` handler to actually draw the respective widgets, and `DefineVisuallyWidget` will also implement handlers for mouse events, allowing the user to drag around the basis vectors.

It's also worth noting here that I don't currently know how I'm going to implement the transformation of arbitrary polygons. It will likely consist of an attribute in `VisualizeTransformationWidget` which is a list of points, and these points can be dragged around with mouse event handlers and then the transformed versions can be rendered, but I'm not yet sure about how I'm going to implement it.

## 2.3 Algorithm design

This section will be completed later.

## 2.4 Usability features

My main concern in terms of usability is colour. In the 3blue1brown videos on linear algebra, red and green are used for the basis vectors, but these colours are often hard to distinguish in most common forms of colour blindness. The most common form is deuteranopia[25], which makes red and green look incredibly similar. I will use blue and red for my basis vectors. These colours are easy to distinguish for people with deuteranopia and protanopia - the two most common forms of colour blindness. Tritanopia makes it harder to distinguish blue and yellow, but my colour scheme is still be accessible for people with tritanopia, as red and blue are very distinct in this form of colour blindness.

I will probably use green for the eigenvectors and eigenlines, which will be hard to distinguish from the red basis vector for people with red-green colour blindness, but I think that the basis vectors and

eigenvectors/eigenlines will look physically different enough from each other that the colour shouldn't be too much of a problem. Additionally, I will use a tool called Color Oracle[11] to make sure that my app is accessible to people with different forms of colour blindness<sup>6</sup>.

Another solution would be to have one default colour scheme, and allow the user to change the colour scheme to something more accessible for colour blind people, but I don't see the point in this. I think it's easier for colour blind people to just have the main colour scheme be accessible, and it's not really an inconvenience to non-colour blind people, so I think this is the best option.

The layout of my app will be self-consistent and follow standard conventions. I will have a menu bar at the top of the main window for actions like saving and loading, as well as accessing the tutorial (which will also be accessible by pressing **F1** at any point) and documentation. The dialogs will always have the confirm button in the bottom right and the cancel button just to the left of that. They will also have the matrix name drop-down on the left. This consistency will make the app easier to learn and understand.

I will also have hotkeys for everything that can have hotkeys - buttons, checkboxes, etc. This makes my life easier, since I'm used to having hotkeys for everything, and thus makes the app faster to test because I don't need to click everything. This also makes things easier for other people like me, who prefer to stay at the keyboard and not use the mouse. Obviously a mouse will be required for things like dragging basis vectors and polygon vertices, but hotkeys will be available wherever possible to help people who don't like using the mouse or find it difficult.

## 2.5 Variables and validation

This project won't actually have many variables. The main ones will be instance attributes on the `LintransMainWindow` class. It will have a `MatrixWrapper` instance, a `DisplaySettings` instance, and a `GlobalSettings` instance. These will handle the matrices and various settings respectively. Having these as instance attributes allows them to be referenced from any method in the class, and Qt5 uses lots of slots (basically callback methods) and handlers, so it's good to be able to access the attributes I need right there rather than having to pass them around from method to method.

The `MatrixWrapper` class will have a dictionary of names and matrices. The names will be single letters<sup>7</sup> and the matrices will be of type `MatrixType`. This will be a custom type alias representing a  $2 \times 2$  numpy array of floats. When setting the values for these matrices, I will have to manually check the types. This is because Python has weak typing, and if we got, say, an integer in place of a matrix, then operations would fail when trying to evaluate a matrix expression, and the program would crash. To prevent this, we have to validate the type of every matrix when it's set. I have chosen to use a dictionary here because it makes accessing a matrix by its name easier. We don't have to check against a list of letters and another list of matrices, we just index into the dictionary.

The settings dataclasses will have instance attributes for each setting. Most of these will be booleans, since they will be simple binary options like *Show determinant*, which will be represented with checkboxes in the GUI. The `DisplaySettings` dataclass will also have an attribute of type `int` representing the time in milliseconds to pause during animations.

The `DefineDialog` superclass have a `MatrixWrapper` instance attribute, which will be a parameter in the constructor. When `LintransMainWindow` spawns a definition dialog (which subclasses `DefineDialog`), it will pass in a copy of its own `MatrixWrapper` and connect the `accepted` signal for the dialog. The slot (method) that this signal is connected to will get called when the dialog is closed with the *Confirm* button<sup>8</sup>. This allows the dialog to mutate its own `MatrixWrapper` object and then the main window can copy that mutated version back into its own instance attribute when the user confirms the change. This reduces coupling and makes everything easier to reason about and debug, as well as reducing

---

<sup>6</sup>I actually had to clone a fork of this project[1] to get it working on Ubuntu 20.04 and adapt it slightly to create a working jar file

<sup>7</sup>I would make these char but Python only has a str type for strings

<sup>8</sup>Actually when the dialog calls `.accept()`. The *Confirm* button is actually connected to a method which first takes the info and updates the instance `MatrixWrapper`, and then calls `.accept()`

the number of bugs, since the classes will be independent of each other. In another language, I could pass a pointer to the wrapper and let the dialog mutate it directly, but this is potentially dangerous, and Python doesn't have pointers anyway.

Validation will also play a very big role in the application. The user will be able to enter matrix expressions and these must be validated. I will define a BNF schema and either write my own RegEx or use that BNF to programmatically generate a RegEx. Every matrix expression input will be checked against it. This is to ensure that the matrix wrapper can actually evaluate the expression. If we didn't validate the expression, then the parsing would fail and the program could crash. I've chosen to use a RegEx here rather than any other option because it's the simplest. Creating a RegEx can be difficult, especially for complicated patterns, but it's then easier to use it. Also, Python can compile a RegEx pattern, which makes it much faster to match against, so I will compile the pattern at initialization time and just compare expressions against that pre-compiled pattern, since we know it won't change at runtime.

Additionally, the buttons to render and animate the current matrix expression will only be enabled when the expression is valid. Textboxes in Qt5 emit a `textChanged` signal, which can be connected to a slot. This is just a method that gets called whenever the text in the textbox is changed, so I can use this method to validate the input and update the buttons accordingly. An empty string will count as invalid, so the buttons will be disabled when the box is empty.

I will also apply this matrix expression validation to the textbox in the dialog which allows the user to define a matrix as an expression involving other matrices, and I will validate the input in the numeric definition dialog to make sure that all the inputs are floats. Again, this is to prevent crashes, since a matrix with non-number values in it will likely crash the program.

## 2.6 Iterative test data

In unit testing, I will test the validation, parsing, and generation of rotation matrices from an angle. I will also unit test the utility functions for the GUI, like `is_valid_float`.

For the validation of matrix expressions, I will have data like the following:

Valid	Invalid
"A"	" "
"AB"	"A^"
"-3.4A"	"rot( )"
"A^2"	"A^{2"
"A^T"	"^12"
"A^{-1}"	"A^{3.2}"
"rot(45)"	"A^B"
"3A^{12}"	".A"
"2B^2+A^TC^{-1}"	"--A"
"3.5A^45.6rot(19.2^T-B^-14.1C^5"	"A--B"

This list is not exhaustive, mostly to save space and time, but the full unit testing code is included in appendix B.

The invalid expressions presented here have been chosen to be almost valid, but not quite. They are edge cases. I will also test blatantly invalid expressions like "This is a matrix expression" to make sure the validation works.

Here's an example of some test data for parsing:

Input	Expected
"A"	[[("", "A", "")]]
"AB"	[[("", "A", ""), ("", "B", "")]]
"2A+B^2"	[[("2", "A", ""), ("", "B", "2")]]
"3A^T2.4B^{-1}-C"	[[("3", "A", "T"), ("2.4", "B", "-1")], [("-1", "C", "")]]

The parsing output is pretty verbose and this table doesn't have enough space for most of the more complicated inputs, so here's a monster one:

"2.14A^{3} 4.5rot(14.5)^{-1} + 8.5B^T 5.97C^{14} - 3.14D^{-1} 6.7E^T"

which should parse to give:

[[("2.14", "A", "3"), ("4.5", "rot(14.5)", "-1")], [("8.5", "B", "T"), ("5.97", "C", "14")],  
[("-3.14", "D", "-1"), ("6.7", "E", "T")]]

Any invalid expression will also raise a parse error, so I will check every invalid input previously mentioned and make sure it raises the appropriate error.

Again, this section is brief to save space and time. All unit tests are included in appendix B.

## 2.7 Post-development test data

This section will be completed later.

### 3 Development

Please note, throughout this section, every code snippet will have two comments at the top. The first is the git commit hash that the snippet was taken from<sup>9</sup>. The second comment is the file name. The line numbers of the snippet reflect the line numbers of the file from where the snippet was taken. After a certain point, I introduced copyright comments at the top of every file. These are always omitted here.

#### 3.1 Matrices backend

##### 3.1.1 MatrixWrapper class

The first real part of development was creating the `MatrixWrapper` class. It needs a simple instance dictionary to be created in the constructor, and it needs a way of accessing the matrices. I decided to use Python's `__getitem__()` and `__setitem__()` special methods[15] to allow indexing into a `MatrixWrapper` object like `wrapper['M']`. This simplifies using the class.

```
# 29ec1fedbf307e3b7ca731c4a381535fec899b0b
# src/lintrans/matrices/wrapper.py

1  """A module containing a simple MatrixWrapper class to wrap matrices and context."""
2
3  import numpy as np
4
5  from lintrans.typing import MatrixType
6
7
8  class MatrixWrapper:
9      """A simple wrapper class to hold all possible matrices and allow access to them."""
10
11     def __init__(self):
12         """Initialise a MatrixWrapper object with a matrices dict."""
13         self._matrices: dict[str, MatrixType | None] = {
14             'A': None, 'B': None, 'C': None, 'D': None,
15             'E': None, 'F': None, 'G': None, 'H': None,
16             'I': np.eye(2), # I is always defined as the identity matrix
17             'J': None, 'K': None, 'L': None, 'M': None,
18             'N': None, 'O': None, 'P': None, 'Q': None,
19             'R': None, 'S': None, 'T': None, 'U': None,
20             'V': None, 'W': None, 'X': None, 'Y': None,
21             'Z': None
22         }
23
24     def __getitem__(self, name: str) -> MatrixType | None:
25         """Get the matrix with `name` from the dictionary.
26
27         Raises:
28             KeyError:
29                 If there is no matrix with the given name
30         """
31         return self._matrices[name]
32
33     def __setitem__(self, name: str, new_matrix: MatrixType) -> None:
34         """Set the value of matrix `name` with the new_matrix.
35
36         Raises:
37             ValueError:
38                 If `name` isn't a valid matrix name
39         """
40         name = name.upper()
41
42         if name == 'I' or name not in self._matrices:
43             raise NameError('Matrix name must be a capital letter and cannot be "I"')
```

<sup>9</sup>A history of all commits can be found in the GitHub repository[2]

```

44
45         self._matrices[name] = new_matrix

```

This code is very simple. The constructor (`__init__()`) creates a dictionary of matrices which all start out as having no value, except the identity matrix **I**. The `__getitem__()` and `__setitem__()` methods allow the user to easily get and set matrices just like a dictionary, and `__setitem__()` will raise an error if the name is invalid. This is a very early prototype, so it doesn't validate the type of whatever the user is trying to assign it to yet. This validation will come later.

I could make this class subclass `dict`, since it's basically just a dictionary at this point, but I want to extend it with much more functionality later, so I chose to handle the dictionary stuff myself.

I then had to write unit tests for this class, and I chose to do all my unit tests using a framework called `pytest`.

```

# 29ec1fedbf307e3b7ca731c4a381535fec899b0b
# tests/test_matrix_wrapper.py

1  """Test the MatrixWrapper class."""
2
3  import numpy as np
4  import pytest
5  from lintrans.matrices import MatrixWrapper
6
7  valid_matrix_names = 'ABCDEFGHJKLMNPOQRSTUVWXYZ'
8  test_matrix = np.array([[1, 2], [4, 3]])
9
10
11 @pytest.fixture
12 def wrapper() -> MatrixWrapper:
13     """Return a new MatrixWrapper object."""
14     return MatrixWrapper()
15
16
17 def test_get_matrix(wrapper) -> None:
18     """Test MatrixWrapper.__getitem__()."""
19     for name in valid_matrix_names:
20         assert wrapper[name] is None
21
22     assert (wrapper['I'] == np.array([[1, 0], [0, 1]])).all()
23
24
25 def test_get_name_error(wrapper) -> None:
26     """Test that MatrixWrapper.__getitem__() raises a KeyError if called with an invalid name."""
27     with pytest.raises(KeyError):
28         _ = wrapper['bad name']
29         _ = wrapper['123456']
30         _ = wrapper['Th15 Is an 1nV@l1D n@m3']
31         _ = wrapper['abc']
32
33
34 def test_set_matrix(wrapper) -> None:
35     """Test MatrixWrapper.__setitem__()."""
36     for name in valid_matrix_names:
37         wrapper[name] = test_matrix
38         assert (wrapper[name] == test_matrix).all()
39
40
41 def test_set_identity_error(wrapper) -> None:
42     """Test that MatrixWrapper.__setitem__() raises a NameError when trying to assign to I."""
43     with pytest.raises(NameError):
44         wrapper['I'] = test_matrix
45
46
47 def test_set_name_error(wrapper) -> None:
48     """Test that MatrixWrapper.__setitem__() raises a NameError when trying to assign to an invalid name."""
49     with pytest.raises(NameError):
50         wrapper['bad name'] = test_matrix
51         wrapper['123456'] = test_matrix

```

```

52     wrapper['Th15 Is an 1nV@l1D n@m3'] = test_matrix
53     wrapper['abc'] = test_matrix

```

These tests are quite simple and just ensure that the expected behaviour works the way it should, and that the correct errors are raised when they should be. It verifies that matrices can be assigned, that every valid name works, and that the identity matrix **I** cannot be assigned to.

The function decorated with `@pytest.fixture` allows functions to use a parameter called `wrapper` and `pytest` will automatically call this function and pass it as that parameter. It just saves on code repetition.

### 3.1.2 Rudimentary parsing and evaluating

This first thing I did here was improve the `__setitem__()` and `__getitem__()` methods to validate input and easily get transposes and simple rotation matrices.

```

# f89fc9fd8d5917d07557fc50df3331123b55ad6b
# src/lintrans/matrices/wrapper.py

60     def __setitem__(self, name: str, new_matrix: MatrixType) -> None:
61         """Set the value of matrix 'name' with the new_matrix.
62
63         :param str name: The name of the matrix to set the value of
64         :param MatrixType new_matrix: The value of the new matrix
65         :rtype: None
66
67         :raises NameError: If the name isn't a valid matrix name or is 'I'
68         """
69         if name not in self._matrices.keys():
70             raise NameError('Matrix name must be a single capital letter')
71
72         if name == 'I':
73             raise NameError('Matrix name cannot be "I"')
74
75         # All matrices must have float entries
76         a = float(new_matrix[0][0])
77         b = float(new_matrix[0][1])
78         c = float(new_matrix[1][0])
79         d = float(new_matrix[1][1])
80
81         self._matrices[name] = np.array([[a, b], [c, d]])

```

In this method, I'm now casting all the values to floats. This is very simple validation, since this cast will raise **ValueError** if it fails to cast the value to a float. I should've declared `:raises ValueError:` in the docstring, but this was an oversight at the time.

```

# f89fc9fd8d5917d07557fc50df3331123b55ad6b
# src/lintrans/matrices/wrapper.py

27     def __getitem__(self, name: str) -> Optional[MatrixType]:
28         """Get the matrix with the given name.
29
30         If it is a simple name, it will just be fetched from the dictionary.
31         If the name is followed with a 't', then we will return the transpose of the named matrix.
32         If the name is 'rot()', with a given angle in degrees, then we return a new rotation matrix with that angle.
33
34         :param str name: The name of the matrix to get
35         :returns: The value of the matrix (may be none)
36         :rtype: Optional[MatrixType]
37
38         :raises NameError: If there is no matrix with the given name
39         """
40         # Return a new rotation matrix

```

```

41         match = re.match(r'rot\\((\\d+)\\)', name)
42         if match is not None:
43             return create_rotation_matrix(float(match.group(1)))
44
45         # Return the transpose of this matrix
46         match = re.match(r'([A-Z])t', name)
47         if match is not None:
48             matrix = self[match.group(1)]
49
50             if matrix is not None:
51                 return matrix.T
52             else:
53                 return None
54
55         if name not in self._matrices:
56             raise NameError(f'Unrecognised matrix name "{name}"')
57
58         return self._matrices[name]

```

This `__getitem__()` method now allows for easily accessing transposes and rotation matrices by checking input with regular expressions. This makes getting matrices easier and thus makes evaluating full expressions simpler.

The `create_rotation_matrix()` method is also defined in this file and just uses the  $\begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}$  formula from before:

```

# f89fc9fd8d5917d07557fc50df3331123b55ad6b
# src/lintrans/matrices/wrapper.py

158 def create_rotation_matrix(angle: float) -> MatrixType:
159     """Create a matrix representing a rotation by the given number of degrees anticlockwise.
160
161     :param float angle: The number of degrees to rotate by
162     :returns MatrixType: The resultant rotation matrix
163     """
164     rad = np.deg2rad(angle)
165     return np.array([
166         [np.cos(rad), -1 * np.sin(rad)],
167         [np.sin(rad), np.cos(rad)]
168     ])

```

At this stage, I also implemented a simple parser and evaluator using regular expressions. It's not great and it's not very flexible, but it can evaluate simple expressions.

```

# f89fc9fd8d5917d07557fc50df3331123b55ad6b
# src/lintrans/matrices/wrapper.py

83 def parse_expression(self, expression: str) -> MatrixType:
84     """Parse a given expression and return the matrix for that expression.
85
86     Expressions are written with standard LaTeX notation for exponents. All whitespace is ignored.
87
88     Here is documentation on syntax:
89         A single matrix is written as 'A'.
90         Matrix A multiplied by matrix B is written as 'AB'
91         Matrix A plus matrix B is written as 'A+B'
92         Matrix A minus matrix B is written as 'A-B'
93         Matrix A squared is written as 'A^2'
94         Matrix A to the power of 10 is written as 'A^10' or 'A^{10}'
95         The inverse of matrix A is written as 'A^-1' or 'A^{-1}'
96         The transpose of matrix A is written as 'A^T' or 'At'
97
98     :param str expression: The expression to be parsed
99     :returns MatrixType: The matrix result of the expression
100
101     :raises ValueError: If the expression is invalid, such as an empty string
102     """

```

143
144         # This list is a list of tuple, where each tuple is (a float multiplier,
145         # the matrix (gotten from the wrapper's __getitem__()), the integer power)
146         matrices: list[tuple[float, MatrixType, int]]
147         matrices = [(float(t[0]), self[t[1]], int(t[2])) for t in string_matrices]
148
149         # Process the matrices and make actual MatrixType objects
150         processed_matrices: list[MatrixType] = [t[0] * np.linalg.matrix_power(t[1], t[2]) for t in matrices]
151
152         # Add this matrix product to the sum total
153         matrix_sum += reduce(lambda m, n: m @ n, processed_matrices)
154
155     return matrix_sum

```

I think the comments in the code speak for themselves, but we basically split the expression up into groups to be added, and then for each group, we multiply every matrix in that group to get its value, and then add all these values together at the end.

This code is objectively bad. At the time of writing, it's now quite old, so I can say that. This code has no real error handling, and line 127 introduces the glaring error that 'A++B' is now a valid expression because we disregard empty strings. Not to mention the fact that the method is called `parse_expression()` but actually evaluates an expression. All these issues will be fixed in the future, but this was the first implementation of matrix evaluation, and it does the job decently well.

I then implemented several tests for this parsing.

```

# 60e0c713b244e097bab8ee0f71142b709fde1a8b
# tests/test_matrix_wrapper_parse_expression.py

135     assert (wrapper.parse_expression('G^{-2}') == la.matrix_power(wrapper['G'], -2)).all()

```

These test lots of simple expressions, but don't test any more complicated expressions, nor do they test any validation, mostly because validation doesn't really exist at this point. 'A++B' is still a valid expression and is equivalent to 'A+B'.

### 3.1.3 Simple matrix expression validation

My next major step was to implement proper parsing, but I procrastinated for a while and first implemented proper validation.

```
# 39b918651f60bc72bc19d2018075b24a6fc3af17
# src/lintrans/_parse/matrices.py

def compile_valid_expression_pattern() -> Pattern[str]:
    """Compile the single regular expression that will match a valid matrix expression."""
    digit_no_zero = '[123456789]'
    digits = '\\d+'
    integer_no_zero = '-?' + digit_no_zero + '(' + digits + ')?'
    real_number = f'({integer_no_zero}(\\.{digits})?|-?0?\\.{digits})'

    index_content = f'({integer_no_zero}|T)'
    index = f'(^\\^\\^{{{index_content}\\}\\}\\^{{{index_content}}}|t)'
    matrix_identifier = f'([A-Z]|rot\\(\\{real_number\\}\\))'
    matrix = '(' + real_number + '?' + matrix_identifier + index + ')?'
    expression = f'{matrix}+(\\+|-){matrix}+*'

    return re.compile(expression)

# This is an expensive pattern to compile, so we compile it when this module is initialized
valid_expression_pattern = compile_valid_expression_pattern()

def validate_matrix_expression(expression: str) -> bool:
    """Validate the given matrix expression.

    This function simply checks the expression against a BNF schema. It is not
    aware of which matrices are actually defined in a wrapper. For an aware
    version of this function, use the MatrixWrapper().is_valid_expression() method.

    Here is the schema for a valid expression given in a version of BNF:

    expression      ::= matrices { ( "+" | "-" ) matrices };
    matrices         ::= matrix { matrix };
    matrix           ::= [ real_number ] matrix_identifier [ index ];
    matrix_identifier ::= "A" .. "Z" | "rot(" real_number ")";
    index            ::= "^{" index_content "}" | "^" index_content | "t";
    index_content    ::= integer_not_zero | "T";

    digit_no_zero    ::= "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
    digit            ::= "0" | digit_no_zero;
    digits           ::= digit | digits digit;
    integer_not_zero  ::= [ "-" ] digit_no_zero [ digits ];
    real_number       ::= ( integer_not_zero [ "." digits ] | [ "-" ] [ "0" ] "." digits );

    :param str expression: The expression to be validated
    :returns bool: Whether the expression is valid according to the schema
    """
    match = valid_expression_pattern.match(expression)
    return match is not None if match else False
```

Here, I'm using a BNF schema to programmatically generate a regular expression. I use a function to generate this pattern and assign it to a variable when the module is initialized. This is because the pattern compilation is expensive and it's more efficient to compile the pattern once and then just use it in the `validate_matrix_expression()` function.

I also created a method `is_valid_expression()` in `MatrixWrapper`, which just validates a given expression. It uses the aforementioned `validate_matrix_expression()` and also checks that every matrix referenced in the expression is defined in the wrapper.

```
# 39b918651f60bc72bc19d2018075b24a6fc3af17
# src/lintrans/matrices/wrapper.py
```

```

99     def is_valid_expression(self, expression: str) -> bool:
100         """Check if the given expression is valid, using the context of the wrapper.
101
102         This method calls _parse.validate_matrix_expression(), but also ensures
103         that all the matrices in the expression are defined in the wrapper.
104
105         :param str expression: The expression to validate
106         :returns bool: Whether the expression is valid according the schema
107         """
108         # Get rid of the transposes to check all capital letters
109         expression = re.sub(r'\^T', 't', expression)
110         expression = re.sub(r'\^{T}', 't', expression)
111
112         # Make sure all the referenced matrices are defined
113         for matrix in {x for x in expression if re.match('[A-Z]', x)}:
114             if self[matrix] is None:
115                 return False
116
117         return _parse.validate_matrix_expression(expression)

```

I then implemented some simple tests to make sure the function works with valid and invalid expressions.

```

# a0fb029f7da995803c24ee36e7e8078e5621f676
# tests/_parse/test_parse_and_validate_expression.py

1  """Test the _parse.matrices module validation and parsing."""
2
3  import pytest
4  from lintrans._parse import validate_matrix_expression
5
6  valid_inputs: list[str] = [
7      'A', 'AB', '3A', '1.2A', '-3.4A', 'A^2', 'A^-1', 'A^{-1}',
8      'A^12', 'A^T', 'A^{5}', 'A^{T}', '4.3A^7', '9.2A^{18}',
9
10     'rot(45)', 'rot(12.5)', '3rot(90)',
11     'rot(135)^3', 'rot(51)^T', 'rot(-34)^-1',
12
13     'A+B', 'A+2B', '4.3A+9B', 'A^2+B^T', '3A^7+0.8B^{16}',
14     'A-B', '3A-4B', '3.2A^3-16.79B^T', '4.752A^{17}-3.32B^{36}',
15     'A--1B', '-A', '--1A'
16
17     '3A4B', 'A^TB', 'A^{T}B', '4A^6B^3',
18     '2A^{3}4B^5', '4rot(90)^3', 'rot(45)rot(13)',
19     'Arot(90)', 'AB^2', 'A^2B^2', '8.36A^T3.4B^12',
20
21     '3.5A^{4}5.6rot(19.2)^T-B^{-1}4.1C^5',
22 ]
23
24  invalid_inputs: list[str] = [
25      '', 'rot()', 'A^', 'A^1.2', 'A^{3.4}', '1,2A', 'ro(12)', '5', '12^2',
26      '^T', '^12}', 'A^{13}', 'A^3}', 'A^A', '^2', 'A--B', '--A'
27
28      'This is 100% a valid matrix expression, I swear'
29  ]
30
31
32  @pytest.mark.parametrize('inputs,output', [(valid_inputs, True), (invalid_inputs, False)])
33  def test_validate_matrix_expression(inputs: list[str], output: bool) -> None:
34      """Test the validate_matrix_expression() function."""
35      for inp in inputs:
36          assert validate_matrix_expression(inp) == output

```

Here, we test some valid data, some definitely invalid data, and some edge cases. At this stage, 'A--1B' was considered a valid expression. This was a quirk of the validator at the time, but I fixed it later. This should obviously be an invalid expression, especially since 'A--B' is considered invalid, but 'A--1B' is valid.

The `@pytest.mark.parametrize` decorator on line 32 means that `pytest` will run one test for valid inputs, and then another test for invalid inputs, and these will count as different tests. This makes it easier to see which tests failed and then debug the app.

### 3.1.4 Parsing matrix expressions

Parsing is quite an interesting problem and something I didn't feel able to tackle head-on, so I wrote the unit tests first. I had a basic idea of what I wanted the parser to return, but no real idea of how to implement that. My unit tests looked like this:

```
# e9f7a81892278fe70684562052f330fb3a02bf9b
# tests/_parse/test_parse_and_validate_expression.py

expressions_and_parsed_expressions: list[tuple[str, MatrixParseList]] = [
    # Simple expressions
    ('A', [(('', 'A', '')]]),
    ('A^2', [(('', 'A', '2')]]),
    ('A^{2}', [(('', 'A', '2')]]),
    ('3A', [(('3', 'A', '')]]),
    ('1.4A^3', [(('1.4', 'A', '3')]]),

    # Multiplications
    ('4A^3 6B^2', [(('4', 'A', '3'), ('6', 'B', '2')]]),
    ('4.2A^{T} 6.1B^{-1}', [(('4.2', 'A', 'T'), ('6.1', 'B', '-1')]]),
    ('-1.2A^2 rot(45)^2', [(('1.2', 'A', '2'), ('', 'rot(45)', '2')]]),
    ('3.2A^T 4.5B^{5} 9.6rot(121.3)', [(('3.2', 'A', 'T'), ('4.5', 'B', '5'), ('9.6', 'rot(121.3)', ''))]]),
    ('-1.18A^{-2} 0.1B^{2} 9rot(34.6)^{-1}', [(('1.18', 'A', '-2'), ('0.1', 'B', '2'), ('9', 'rot(34.6)', '-1')]]),

    # Additions
    ('A + B', [(('', 'A', ''), ('', 'B', ''))]]),
    ('A + B - C', [(('', 'A', ''), ('', 'B', '')), (('1', 'C', ''))]]),
    ('2A^3 + 8B^T - 3C^{-1}', [(('2', 'A', '3'), ('8', 'B', 'T'), ('3', 'C', '-1')]]),

    # Additions with multiplication
    ('2.14A^3 4.5rot(14.5)^{-1} + 8B^T - 3C^{-1}', [(('2.14', 'A', '3'), ('4.5', 'rot(14.5)', '-1'), ('8', 'B', 'T'), ('3', 'C', '-1')]]),
    ('2.14A^3 4.5rot(14.5)^{-1} + 8.5B^T 5.97C^4 - 3.14D^{-1} 6.7E^T', [(('2.14', 'A', '3'), ('4.5', 'rot(14.5)', '-1'), ('8.5', 'B', 'T'), ('5.97', 'C', '4'), ('3.14', 'D', '-1'), ('6.7', 'E', 'T')]]),
]

@pytest.mark.skip(reason='parse_matrix_expression() not implemented')
def test_parse_matrix_expression() -> None:
    """Test the parse_matrix_expression() function."""
    for expression, parsed_expression in expressions_and_parsed_expressions:
        # Test it with and without whitespace
        assert parse_matrix_expression(expression) == parsed_expression
        assert parse_matrix_expression(expression.replace(' ', '')) == parsed_expression
```

I just had example inputs and what I expected as output. I also wanted the parser to ignore whitespace. The decorator on line 69 just skips the test because the parser wasn't implemented yet.

When implementing the parser, I first had to tighten up validation to remove anomalies like `'A--1B'` being valid. I did this by factoring out the optional minus signs from being part of a number, to being optionally in front of a number. This eliminated this kind of repetition and made `'A--1B'` invalid, as it should be.

```
# fd80d8d3b0e975e92dcc7c10f1f0f1276879f408
# src/lintrans/_parse/matrices.py

def compile_valid_expression_pattern() -> Pattern[str]:
    """Compile the single regular expression that will match a valid matrix expression."""
    digit_no_zero = '[123456789]'
    digits = '\\d+'

```

```

36 integer_no_zero = digit_no_zero + '(' + digits + ')?'
37 real_number = f'({integer_no_zero}(\.{digits})?|0?\.{digits})'
38
39 index_content = f'(-?{integer_no_zero}|T)'
40 index = f'(\^\^\{{index_content}\}\^\^\{{index_content}}|t)'
41 matrix_identifier = f'([A-Z]|rot\((-?{real_number}\)\)'
42 matrix = '(' + real_number + '?' + matrix_identifier + index + '?'
43 expression = f'-?{matrix}+(\(|\+|\-){matrix})*'
44
45 return re.compile(expression)

```

The code can be a bit hard to read with all the RegEx stuff, but the BNF illustrates these changes nicely.

Compare the old version:

```

# 39b918651f60bc72bc19d2018075b24a6fc3af17
# src/lintrans/_parse/matrices.py

38 expression      ::= matrices { ( "+" | "-" ) matrices };
39 matrices        ::= matrix { matrix };
40 matrix           ::= [ real_number ] matrix_identifier [ index ];
41 matrix_identifier ::= "A" .. "Z" | "rot(" real_number ")";
42 index            ::= "^{" index_content "}" | "^" index_content | "t";
43 index_content    ::= integer_not_zero | "T";
44
45 digit_no_zero    ::= "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
46 digit            ::= "0" | digit_no_zero;
47 digits           ::= digit | digits digit;
48 integer_not_zero ::= [ "-" ] digit_no_zero [ digits ];
49 real_number      ::= ( integer_not_zero [ "." digits ] | [ "-" ] [ "0" ] "." digits );

```

to the new version:

```

# fd80d8d3b0e975e92dcc7c10f1f0f1276879f408
# src/lintrans/_parse/matrices.py

61 expression      ::= [ "-" ] matrices { ( "+" | "-" ) matrices };
62 matrices        ::= matrix { matrix };
63 matrix           ::= [ real_number ] matrix_identifier [ index ];
64 matrix_identifier ::= "A" .. "Z" | "rot(" [ "-" ] real_number ")";
65 index            ::= "^{" index_content "}" | "^" index_content | "t";
66 index_content    ::= [ "-" ] integer_not_zero | "T";
67
68 digit_no_zero    ::= "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
69 digit            ::= "0" | digit_no_zero;
70 digits           ::= digit | digits digit;
71 integer_not_zero ::= digit_no_zero [ digits ];
72 real_number      ::= ( integer_not_zero [ "." digits ] | [ "0" ] "." digits );

```

Then once I'd fixed the validation, I could implement the parser itself.

```

# fd80d8d3b0e975e92dcc7c10f1f0f1276879f408
# src/lintrans/_parse/matrices.py

86 def parse_matrix_expression(expression: str) -> MatrixParseList:
87     """Parse the matrix expression and return a list of results.
88
89     The return value is a list of results. This results list contains lists of tuples.
90     The top list is the expressions that should be added together, and each sublist
91     is expressions that should be multiplied together. These expressions to be
92     multiplied are tuples, where each tuple is (multiplier, matrix identifier, index).
93     The multiplier can be any real number, the matrix identifier is either a named
94     matrix or a new rotation matrix declared with 'rot()', and the index is an
95     integer or 'T' for transpose.
96

```

```

97     :param str expression: The expression to be parsed
98     :returns MatrixParseTuple: A list of results
99     """
100    # Remove all whitespace
101    expression = re.sub(r'\s', '', expression)
102
103    # Check if it's valid
104    if not validate_matrix_expression(expression):
105        raise MatrixParseError('Invalid expression')
106
107    # Wrap all exponents and transposition powers with {}
108    expression = re.sub(r'(?<=\^)(-?\d+|T)(?=[^}]|$)', r'{\g<0>}', expression)
109
110    # Remove any standalone minuses
111    expression = re.sub(r'-(?=[A-Z])', '-1', expression)
112
113    # Replace subtractions with additions
114    expression = re.sub(r'-(?=\d+\.?\d*([A-Z]|rot))', '+-', expression)
115
116    # Get rid of a potential leading + introduced by the last step
117    expression = re.sub(r'^+', '', expression)
118
119    return [
120        [
121            # The tuple returned by re.findall is (multiplier, matrix identifier, full index, stripped index),
122            # so we have to remove the full index, which contains the {}
123            (t[0], t[1], t[3])
124            for t in re.findall(r'(-?\d+\.?\d*)?([A-Z]|rot\(-?\d+\.?\d*\))(\^{(-?\d+|T)})?', group)
125        ]
126        # We just split the expression by '+' to have separate groups
127        for group in expression.split('+')
128    ]

```

It works similarly to the old `MatrixWrapper.parse_expression()` method in §3.1.2 but with a powerful list comprehension at the end. It splits the expression up into groups and then uses some RegEx magic to find all the matrices in these groups as a tuple.

This method passes all the unit tests, as expected.

My next step was then to rewrite the evaluation to use this new parser, like so (method name and docstring removed):

```

# a453774bcd824676461f9b9b441d7b94969ea55
# src/lintrans/matrices/wrapper.py

168    if not self.is_valid_expression(expression):
169        raise ValueError('The expression is invalid')
170
171    parsed_result = _parse.parse_matrix_expression(expression)
172    final_groups: list[list[MatrixType]] = []
173
174    for group in parsed_result:
175        f_group: list[MatrixType] = []
176
177        for matrix in group:
178            if matrix[2] == 'T':
179                m = self[matrix[1]]
180                assert m is not None
181                matrix_value = m.T
182            else:
183                matrix_value = np.linalg.matrix_power(self[matrix[1]],
184                1 if (index := matrix[2]) == '' else int(index))
185
186            matrix_value *= 1 if (multiplier := matrix[0]) == '' else float(multiplier)
187            f_group.append(matrix_value)
188
189        final_groups.append(f_group)
190
191    return reduce(add, [reduce(matmul, group) for group in final_groups])

```

Here, we go through the list of tuples and evaluate the matrix represented by each tuple, putting this together in a list as we go. Then at the end, we simply reduce the sublists and then reduce these new matrices using a list comprehension in the `reduce()` call using `add` and `matmul` from the `operator` library. It's written in a functional programming style, and it passes all the previous tests.

## 3.2 Initial GUI

### 3.2.1 First basic GUI

The discrepancy in all the GUI code between `snake_case` and `camelCase` is because Qt5 was originally a C++ framework that was adapted into PyQt5 for Python. All the Qt API is in `camelCase`, but my Python code is in `snake_case`.

```
# 93ce763f7b993439fc0da89fad39456d8cc4b52c
# src/lintrans/gui/main_window.py

1 """The module to provide the main window as a QMainWindow object."""
2
3 import sys
4
5 from PyQt5 import QtCore, QtGui, QtWidgets
6 from PyQt5.QtWidgets import QApplication, QHBoxLayout, QMainWindow, QVBoxLayout
7
8 from lintrans.matrices import MatrixWrapper
9
10
11 class LintransMainWindow(QMainWindow):
12     """The class for the main window in the lintrans GUI."""
13
14     def __init__(self):
15         """Create the main window object, creating every widget in it."""
16         super().__init__()

157         sys.exit(app.exec_())
158
159
160 if __name__ == '__main__':
161     main()

```

Figure 3.1: The first version of the GUI

A lot of the methods here don't have implementations yet, but they will. This version is just a very early prototype to get a rough draft of the GUI.

I create the widgets and layouts in the constructor as well as configuring all of them. The most important non-constructor method is `update_render_buttons()`. It gets called whenever the text in `text_input_expression` is changed. This happens because we connect it to the `textChanged` signal on line 32.

The big white box here will eventually be replaced with an actual viewport. This is just a prototype.

### 3.2.2 Numerical definition dialog

My next major addition was a dialog that would allow the user to define a matrix numerically.

```

# cedbd3ed126a1183f197c27adf6dabb4e5d301c7
# src/lintrans/gui/dialogs/define_new_matrix.py

1 """The module to provide dialogs for defining new matrices."""
2
3 from numpy import array
4 from PyQt5 import QtGui, QtWidgets
5 from PyQt5.QtWidgets import QDialog, QGridLayout, QHBoxLayout, QVBoxLayout

```

```
6
7 from lintrans.matrices import MatrixWrapper
8
9 ALPHABET_NO_I = 'ABCDEFGHJKLMNOPQRSTUVWXYZ'
10
11
12 def is_float(string: str) -> bool:
13     """Check if a string is a float."""
14     try:
15         float(string)
16         return True
17     except ValueError:
18         return False
19
20
21 class DefineNumericallyDialog(QDialog):
22     """The dialog class that allows the user to define a new matrix numerically."""
23
24     def __init__(self, matrix_wrapper: MatrixWrapper, *args, **kwargs):
25         """Create the dialog, but don't run it yet.
26
27         :param matrix_wrapper: The MatrixWrapper that this dialog will mutate
28         :type matrix_wrapper: MatrixWrapper
29         """
30         super().__init__(*args, **kwargs)
31
32         self.matrix_wrapper = matrix_wrapper
33         self.setWindowTitle('Define a matrix')
34
35         # === Create the widgets
36
37         self.button_confirm = QtWidgets.QPushButton(self)
38         self.button_confirm.setText('Confirm')
39         self.button_confirm.setEnabled(False)
40         self.button_confirm.clicked.connect(self.confirm_matrix)
41         self.button_confirm.setToolTip('Confirm this as the new matrix<br><b>(Ctrl + Enter)</b>')
42
43         QtWidgets.QShortcut(QtGui.QKeySequence('Ctrl+Return'), self).activated.connect(self.button_confirm.click)
44
45         self.button_cancel = QtWidgets.QPushButton(self)
46         self.button_cancel.setText('Cancel')
47         self.button_cancel.clicked.connect(self.close)
48         self.button_cancel.setToolTip('Cancel this definition<br><b>(Ctrl + Q)</b>')
49
50         QtWidgets.QShortcut(QtGui.QKeySequence('Ctrl+Q'), self).activated.connect(self.button_cancel.click)
51
52         self.element_tl = QtWidgets.QLineEdit(self)
53         self.element_tl.textChanged.connect(self.update_confirm_button)
54
55         self.element_tr = QtWidgets.QLineEdit(self)

57
58         self.element_bl = QtWidgets.QLineEdit(self)
59         self.element_bl.textChanged.connect(self.update_confirm_button)
60
61         self.element_br = QtWidgets.QLineEdit(self)
62         self.element_br.textChanged.connect(self.update_confirm_button)
63
64         self.matrix_elements = (self.element_tl, self.element_tr, self.element_bl, self.element_br)
65
66         self.letter_combo_box = QtWidgets.QComboBox(self)
67
68         # Everything except I, because that's the identity
69         for letter in ALPHABET_NO_I:
70             self.letter_combo_box.addItem(letter)
71
72         self.letter_combo_box.activated.connect(self.load_matrix)
73
74         # === Arrange the widgets
75
76         self.setContentsMargins(10, 10, 10, 10)
77
78         self.grid_matrix = QGridLayout()
```

```

79         self.grid_matrix.setSpacing(20)
80         self.grid_matrix.addWidget(self.element_tl, 0, 0)
81         self.grid_matrix.addWidget(self.element_tr, 0, 1)
82         self.grid_matrix.addWidget(self.element_bl, 1, 0)
83         self.grid_matrix.addWidget(self.element_br, 1, 1)
84
85         self.hlay_buttons = QHBoxLayout()
86         self.hlay_buttons.setSpacing(20)
87         self.hlay_buttons.addWidget(self.button_cancel)
88         self.hlay_buttons.addWidget(self.button_confirm)
89
90         self.vlay_right = QVBoxLayout()
91         self.vlay_right.setSpacing(20)
92         self.vlay_right.addLayout(self.grid_matrix)
93         self.vlay_right.addLayout(self.hlay_buttons)
94
95         self.hlay_all = QHBoxLayout()
96         self.hlay_all.setSpacing(20)
97         self.hlay_all.addWidget(self.letter_combo_box)
98         self.hlay_all.addLayout(self.vlay_right)
99
100        self.setLayout(self.hlay_all)
101
102        # Finally, we load the default matrix A into the boxes
103        self.load_matrix(0)
104
105    def update_confirm_button(self) -> None:
106        """Enable the confirm button if there are numbers in every box."""
107        for elem in self.matrix_elements:
108            if elem.text() == '' or not is_float(elem.text()):
109                # If they're not all numbers, then we can't confirm it
110                self.button_confirm.setEnabled(False)
111                return
112
113        # If we didn't find anything invalid
114        self.button_confirm.setEnabled(True)
115
116    def load_matrix(self, index: int) -> None:
117        """If the selected matrix is defined, load it into the boxes."""
118        matrix = self.matrix_wrapper[ALPHABET_NO_I[index]]
119
120        if matrix is None:
121            for elem in self.matrix_elements:
122                elem.setText('')
123
124        else:
125            self.element_tl.setText(str(matrix[0][0]))
126            self.element_tr.setText(str(matrix[0][1]))
127            self.element_bl.setText(str(matrix[1][0]))
128            self.element_br.setText(str(matrix[1][1]))
129
130        self.update_confirm_button()
131
132    def confirm_matrix(self) -> None:
133        """Confirm the inputted matrix and assign it to the name."""
134        letter = self.letter_combo_box.currentText()
135        matrix = array([
136            [float(self.element_tl.text()), float(self.element_tr.text())],
137            [float(self.element_bl.text()), float(self.element_br.text())]
138        ])
139
140        self.matrix_wrapper[letter] = matrix
141        self.close()

```

Figure 3.2: The first version of the numerical definition dialog

When I add more definition dialogs, I will factor out a superclass, but this is just a prototype to make sure it all works as intended.

Hopefully the methods are relatively self explanatory, but they're just utility methods to update the GUI when things are changed. We connect the `QLineEdit` widgets to the `update_confirm_button()` slot to make sure the confirm button is always up to date.

The `confirm_matrix()` method just updates the instance's matrix wrapper with the new matrix. We pass a reference to the `LintransMainWindow` instance's matrix wrapper when we open the dialog, so we're just updating the referenced object directly.

In the `LintransMainWindow` class, we're just connecting a lambda slot to the button so that it opens the dialog, as seen here:

```
# cedbd3ed126a1183f197c27adf6dabb4e5d301c7
# src/lintrans/gui/main_window.py

66 self.button_define_numerically.clicked.connect(
67     lambda: DefineNumericallyDialog(self.matrix_wrapper, self).exec()
68 )
```

### 3.2.3 More definition dialogs

I then factored out the constructor into a `DefinedDialog` superclass so that I could easily create other definition dialogs.

```
# 5d04fb7233a03d0cd8fa0768f6387c6678da9df3
# src/lintrans/gui/dialogs/define_new_matrix.py

22 class DefinedDialog(QDialog):
23     """A superclass for definitions dialogs."""
24
25     def __init__(self, matrix_wrapper: MatrixWrapper, *args, **kwargs):
26         """Create the dialog, but don't run it yet.
27
28         :param matrix_wrapper: The MatrixWrapper that this dialog will mutate
29         :type matrix_wrapper: MatrixWrapper
30         """
31         super().__init__(*args, **kwargs)
32
33         self.matrix_wrapper = matrix_wrapper
34         self.setWindowTitle('Define a matrix')
35
36         # === Create the widgets
37
38         self.button_confirm = QtWidgets.QPushButton(self)
39         self.button_confirm.setText('Confirm')
40         self.button_confirm.setEnabled(False)
41         self.button_confirm.clicked.connect(self.confirm_matrix)
42         self.button_confirm.setToolTip('Confirm this as the new matrix<br><b>(Ctrl + Enter)</b>')
43         QShortcut(QKeySequence('Ctrl+Return'), self).activated.connect(self.button_confirm.click)
44
45         self.button_cancel = QtWidgets.QPushButton(self)
46         self.button_cancel.setText('Cancel')
47         self.button_cancel.clicked.connect(self.close)
48         self.button_cancel.setToolTip('Cancel this definition<br><b>(Ctrl + Q)</b>')
49         QShortcut(QKeySequence('Ctrl+Q'), self).activated.connect(self.button_cancel.click)
50
51         self.label_equals = QtWidgets.QLabel()
```

```

52         self.label_equals.setText('=')
53
54         self.letter_combo_box = QtWidgets.QComboBox(self)
55
56         # Everything except I, because that's the identity
57         for letter in ALPHABET_NO_I:
58             self.letter_combo_box.addItem(letter)
59
60         self.letter_combo_box.activated.connect(self.load_matrix)

```

This superclass just has a constructor that subclasses can use. When I added the `DefineAsARotationDialog` class, I also moved the cancel and confirm buttons into the constructor and added abstract methods that all dialog subclasses must implement.

```

# 0d534c35c6a4451e317d41a0d2b3ecb17827b45f
# src/lintrans/gui/dialogs/define_new_matrix.py

61         # === Arrange the widgets
62
63         self.setContentsMargins(10, 10, 10, 10)
64
65         self.horizontal_spacer = QSpacerItem(50, 5, hPolicy=QSizePolicy.Expanding, vPolicy=QSizePolicy.Minimum)
66
67         self.hlay_buttons = QHBoxLayout()
68         self.hlay_buttons.setSpacing(20)
69         self.hlay_buttons.addItem(self.horizontal_spacer)
70         self.hlay_buttons.addWidget(self.button_cancel)
71         self.hlay_buttons.addWidget(self.button_confirm)
72
73         @property
74         def selected_letter(self) -> str:
75             """The letter currently selected in the combo box."""
76             return self.letter_combo_box.currentText()
77
78         @abc.abstractmethod
79         def update_confirm_button(self) -> None:
80             """Enable the confirm button if it should be enabled."""
81             ...
82
83         @abc.abstractmethod
84         def confirm_matrix(self) -> None:
85             """Confirm the inputted matrix and assign it.
86
87             This should mutate self.matrix_wrapper and then call self.accept().
88             """
89             ...

```

I then added the class for the rotation definition dialog.

```

# 0d534c35c6a4451e317d41a0d2b3ecb17827b45f
# src/lintrans/gui/dialogs/define_new_matrix.py

182 class DefineAsARotationDialog(DefinedDialog):
183     """The dialog that allows the user to define a new matrix as a rotation."""
184
185     def __init__(self, matrix_wrapper: MatrixWrapper, *args, **kwargs):
186         """Create the dialog, but don't run it yet."""
187         super().__init__(matrix_wrapper, *args, **kwargs)
188
189         # === Create the widgets
190
191         self.label_equals.setText('= rot(')
192
193         self.text_angle = QtWidgets.QLineEdit(self)
194         self.text_angle.setPlaceholderText('angle')
195         self.text_angle.textChanged.connect(self.update_confirm_button)
196
197         self.label_close_paren = QtWidgets.QLabel(self)

```

```

198         self.label_close_paren.setText(')')
199
200         self.checkbox_radians = QtWidgets.QCheckBox(self)
201         self.checkbox_radians.setText('Radians')
202
203         # === Arrange the widgets
204
205         self.hlay_checkbox_and_buttons = QHBoxLayout()
206         self.hlay_checkbox_and_buttons.setSpacing(20)
207         self.hlay_checkbox_and_buttons.addWidget(self.checkbox_radians)
208         self.hlay_checkbox_and_buttons.addItem(self.horizontal_spacer)
209         self.hlay_checkbox_and_buttons.addLayout(self.hlay_buttons)
210
211         self.hlay_definition = QHBoxLayout()
212         self.hlay_definition.addWidget(self.letter_combo_box)
213         self.hlay_definition.addWidget(self.label_equals)
214         self.hlay_definition.addWidget(self.text_angle)
215         self.hlay_definition.addWidget(self.label_close_paren)
216
217         self.vlay_all = QVBoxLayout()
218         self.vlay_all.setSpacing(20)
219         self.vlay_all.addLayout(self.hlay_definition)
220         self.vlay_all.addLayout(self.hlay_checkbox_and_buttons)
221
222         self.setLayout(self.vlay_all)
223
224     def update_confirm_button(self) -> None:
225         """Enable the confirm button if there is a valid float in the angle box."""
226         self.button_confirm.setEnabled(is_float(self.text_angle.text()))
227
228     def confirm_matrix(self) -> None:
229         """Confirm the inputted matrix and assign it."""
230         self.matrix_wrapper[self.selected_letter] = create_rotation_matrix(
231             float(self.text_angle.text()),
232             degrees=not self.checkbox_radians.isChecked()
233         )
234         self.accept()

```

This dialog class just overrides the abstract methods of the superclass with its own implementations. This will be the pattern that all of the definition dialogs will follow.

It has a checkbox for radians, since this is supported in `create_rotation_matrix()`, but the textbox only supports numbers, so the user would have to calculate some multiple of  $\pi$  and paste in several decimal places. I expect people to only use degrees, because these are easier to use.

Figure 3.3: The first version of the rotation definition dialog

Additionally, I created a helper method in `LintransMainWindow`. Rather than connecting the clicked signal of the buttons to lambdas that instantiate an instance of the `DefineDialog` subclass and call `.exec()` on it, I now connect the clicked signal of the buttons to lambdas that call `self.dialog_define_matrix()` with the specific subclass.

```

# 6269e04d453df7be2d2f9c7ee176e83406cccc139
# src/lintrans/gui/main_window.py

170     def dialog_define_matrix(self, dialog_class: Type[DefineDialog]) -> None:
171         """Open a generic definition dialog to define a new matrix.
172
173         The class for the desired dialog is passed as an argument. We create an
174         instance of this class and the dialog is opened asynchronously and modally
175         (meaning it blocks interaction with the main window) with the proper method
176         connected to the ``dialog.finished`` slot.
177
178         .. note::

```

```

179         ``dialog_class`` must subclass :class:`lintrans.gui.dialogs.define_new_matrix.DefineDialog`.
180
181     :param dialog_class: The dialog class to instantiate
182     :type dialog_class: Type[lintrans.gui.dialogs.define_new_matrix.DefineDialog]
183     """
184     # We create a dialog with a deepcopy of the current matrix_wrapper
185     # This avoids the dialog mutating this one
186     dialog = dialog_class(deepcopy(self.matrix_wrapper), self)
187
188     # .open() is asynchronous and doesn't spawn a new event loop, but the dialog is still modal (blocking)
189     dialog.open()
190
191     # So we have to use the finished slot to call a method when the user accepts the dialog
192     # If the user rejects the dialog, this matrix_wrapper will be the same as the current one, because we copied
193     ↪ it
194     # So we don't care, we just assign the wrapper anyway
195     dialog.finished.connect(lambda: self._assign_matrix_wrapper(dialog.matrix_wrapper))
196
197     def _assign_matrix_wrapper(self, matrix_wrapper: MatrixWrapper) -> None:
198         """Assign a new value to self.matrix_wrapper.
199
200         This is a little utility function that only exists because a lambda
201         callback can't directly assign a value to a class attribute.
202
203         :param matrix_wrapper: The new value of the matrix wrapper to assign
204         :type matrix_wrapper: MatrixWrapper
205         """
206         self.matrix_wrapper = matrix_wrapper

```

I also then implemented a simple `DefineAsAnExpressionDialog`, which evaluates a given expression in the current `MatrixWrapper` context and assigns the result to the given matrix name.

```

# d5f930e15c3c8798d4990486532da46e926a6cb9
# src/lintrans/gui/dialogs/define_new_matrix.py

241 class DefineAsAnExpressionDialog(DefineDialog):
242     """The dialog that allows the user to define a matrix as an expression."""
243
244     def __init__(self, matrix_wrapper: MatrixWrapper, *args, **kwargs):
245         """Create the dialog, but don't run it yet."""
246         super().__init__(matrix_wrapper, *args, **kwargs)
247
248         self.setMinimumWidth(450)
249
250         # === Create the widgets
251
252         self.text_box_expression = QtWidgets.QLineEdit(self)
253         self.text_box_expression.setPlaceholderText('Enter matrix expression...')
254         self.text_box_expression.textChanged.connect(self.update_confirm_button)
255
256         # === Arrange the widgets
257
258         self.hlay_definition.addWidget(self.text_box_expression)
259
260         self.vlay_all = QVBoxLayout()
261         self.vlay_all.setSpacing(20)
262         self.vlay_all.addLayout(self.hlay_definition)
263         self.vlay_all.addLayout(self.hlay_buttons)
264
265         self.setLayout(self.vlay_all)
266
267     def update_confirm_button(self) -> None:
268         """Enable the confirm button if the expression is valid."""
269         self.button_confirm.setEnabled(
270             self.matrix_wrapper.is_valid_expression(self.text_box_expression.text())
271         )
272
273     def confirm_matrix(self) -> None:
274         """Evaluate the matrix expression and assign its value to the chosen matrix."""
275         self.matrix_wrapper[self.selected_letter] = \

```

```

276         self.matrix_wrapper.evaluate_expression(self.text_box_expression.text())
277         self.accept()

```

My next dialog that I wanted to implement was a visual definition dialog, which would allow the user to drag around the basis vectors to define a transformation. However, I would first need to create the `lintrans.gui.plots` package to allow for actually visualizing matrices and transformations.

### 3.3 Visualizing matrices

#### 3.3.1 Asking strangers on the internet for help

After creating most of the GUI skeleton, I wanted to build the viewport. Unfortunately, I had no idea what I was doing.

While looking through the PyQt5 docs, I found a pretty comprehensive explanation of the Qt5 ‘Graphics View Framework’[14], which seemed pretty good, but not really what I was looking for. I wanted a way to easily draw lots of straight, parallel lines. This framework seemed more focussed on manipulating objects on a canvas, almost like sprites. I knew of a different Python library called `matplotlib`, which has various backends available. I learned that it could be embedded in a standard PyQt5 GUI, so I started doing some research.

I didn’t get very far with `matplotlib`. I hadn’t used it much before and it’s designed for visualizing data. It can draw manually defined straight lines on a canvas, but that’s not what it’s designed for and it’s not very good at it. Thankfully, my horrific `matplotlib` code has been lost to time. I used the `Qt5Agg` backend from `matplotlib` to create a custom PyQt5 widget for the GUI and I could graph randomly generated data with it after following a tutorial[13].

I realised that I wasn’t going to get very far with `matplotlib`, but I didn’t know what else to do. I couldn’t find any relevant examples on the internet, so I decided to post a question on a forum myself. I’d had experience with StackOverflow and its unfriendly community before, so I decided to ask the `r/learnpython` subreddit[3].

I only got one response, but it was incredibly helpful. The person told me that if I couldn’t find an easy way to do what I wanted, I could write a custom PyQt5 widget. I knew this was possible with a class that just inherited from `QWidget`, but had no idea how to actually make something useful. Thankfully, this person provided a link to a GitLab repository of theirs, where they had multiple examples of custom widgets with PyQt5[4].

When looking through this repo, I found out how to draw on a widget like a simple canvas. All I have to do is override the `paintEvent()` method and use a `QPainter` object to draw on the widget. I used this knowledge to start creating the actual viewport for the GUI, starting with the background axes.

#### 3.3.2 Creating the plots package

Initially, the `lintrans.gui.plots` package just has some classes for widgets. `TransformationPlotWidget` acts as a base class and then `ViewTransformationWidget` acts as a wrapper. I will expand this class in the future.

```

# 4af63072b383dc9cef9adbb8900323aa007e7f26
# src/lintrans/gui/plots/plot_widget.py

1  """This module provides the basic classes for plotting transformations."""
2
3  from __future__ import annotations
4
5  from PyQt5.QtCore import Qt

```

```

6  from PyQt5.QtGui import QColor, QPainter, QPaintEvent, QPen
7  from PyQt5.QtWidgets import QWidget
8
9
10 class TransformationPlotWidget(QWidget):
11     """An abstract superclass for plot widgets.
12
13     This class provides a background (untransformed) plane, and all the backend
14     details for a Qt application, but does not provide useful functionality. To
15     be useful, this class must be subclassed and behaviour must be implemented
16     by the subclass.
17
18     .. warning:: This class should never be directly instantiated, only subclassed.
19
20     .. note::
21     I would make this class have ``metaclass=abc.ABCMeta``, but I can't because it subclasses ``QWidget``,
22     and a every superclass of a class must have the same metaclass, and ``QWidget`` is not an abstract class.
23     """
24
25     def __init__(self, *args, **kwargs):
26         """Create the widget, passing ``*args`` and ``**kwargs`` to the superclass constructor (``QWidget``)."""
27         super().__init__(*args, **kwargs)
28
29         self.setAutoFillBackground(True)
30
31         # Set the background to white
32         palette = self.palette()
33         palette.setColor(self.backgroundRole(), Qt.white)
34         self.setPalette(palette)
35
36         # Set the grid colour to grey and the axes colour to black
37         self.grid_colour = QColor(128, 128, 128)
38         self.axes_colour = QColor(0, 0, 0)
39
40         self.grid_spacing: int = 50
41         self.line_width: float = 0.4
42
43     @property
44     def w(self) -> int:
45         """Return the width of the widget."""
46         return self.size().width()
47
48     @property
49     def h(self) -> int:
50         """Return the height of the widget."""
51         return self.size().height()
52
53     def paintEvent(self, e: QPaintEvent):
54         """Handle a ``QPaintEvent`` by drawing the widget."""
55         qp = QPainter()
56         qp.begin(self)
57         self.draw_widget(qp)
58         qp.end()
59
60     def draw_widget(self, qp: QPainter):
61         """Draw the grid and axes in the widget."""
62         qp.setRenderHint(QPainter.Antialiasing)
63         qp.setBrush(Qt.NoBrush)
64
65         # Draw the grid
66         qp.setPen(QPen(self.grid_colour, self.line_width))
67
68         # We draw the background grid, centered in the middle
69         # We deliberately exclude the axes - these are drawn separately
70         for x in range(self.w // 2 + self.grid_spacing, self.w, self.grid_spacing):
71             qp.drawLine(x, 0, x, self.h)
72             qp.drawLine(self.w - x, 0, self.w - x, self.h)
73
74         for y in range(self.h // 2 + self.grid_spacing, self.h, self.grid_spacing):
75             qp.drawLine(0, y, self.w, y)
76             qp.drawLine(0, self.h - y, self.w, self.h - y)
77
78         # Now draw the axes

```

```

79         qp.setPen(QPen(self.axes_colour, self.line_width))
80         qp.drawLine(self.w // 2, 0, self.w // 2, self.h)
81         qp.drawLine(0, self.h // 2, self.w, self.h // 2)
82
83
84     class ViewTransformationWidget(TransformationPlotWidget):
85         """This class is used to visualise matrices as transformations."""
86
87         def __init__(self, *args, **kwargs):
88             """Create the widget, passing ``*args`` and ``**kwargs`` to the superclass constructor."""
89             super().__init__(*args, **kwargs)

```

Figure 3.4: The GUI with background axes

The meat of this class is the `draw_widget()` method. Right now, this method only draws the background axes. My next step is to implement basis vector attributes and draw them in `draw_widget()`. After changing the the `plot` attribute in `LintransMainWindow` to an instance of `ViewTransformationWidget`, the plot was visible in the GUI.

I then refactored the code slightly to rename `draw_widget()` to `draw_background()` and then call it from the `paintEvent()` method in `ViewTransformationWidget`.

### 3.3.3 Implementing basis vectors

My first step in implementing basis vectors was to add some utility methods to convert between coordinate systems. The matrices are using Cartesian coordinates with  $(0,0)$  in the middle, positive  $x$  going to the right, and positive  $y$  going up. However, Qt5 is using standard computer graphics coordinates, with  $(0,0)$  in the top left, positive  $x$  going to the right, and positive  $y$  going down. I needed a way to convert Cartesian ‘grid’ coordinates to Qt5 ‘canvas’ coordinates, so I wrote some little utility methods.

```

# 1fa7e1c61d61cb6aeff773b9698541f82fee39ea
# src/lintrans/gui/plots/plot_widget.py

45     @property
46     def origin(self) -> tuple[int, int]:
47         """Return the canvas coords of the origin."""
48         return self.width() // 2, self.height() // 2
49
50     def trans_x(self, x: float) -> int:
51         """Transform an x coordinate from grid coords to canvas coords."""
52         return int(self.origin[0] + x * self.grid_spacing)
53
54     def trans_y(self, y: float) -> int:
55         """Transform a y coordinate from grid coords to canvas coords."""
56         return int(self.origin[1] - y * self.grid_spacing)
57
58     def trans_coords(self, x: float, y: float) -> tuple[int, int]:
59         """Transform a coordinate in grid coords to canvas coords."""
60         return self.trans_x(x), self.trans_y(y)

```

Once I had a way to convert coordinates, I could add the basis vectors themselves. I did this by creating attributes for the points in the constructor and creating a `transform_by_matrix()` method to change these point attributes accordingly.

```

# 37e7c208a33d7cbbc8e0bb6c94cd889e2918c605
# src/lintrans/gui/plots/plot_widget.py

```

```

92 class ViewTransformationWidget(TransformationPlotWidget):
93     """This class is used to visualise matrices as transformations."""
94
95     def __init__(self, *args, **kwargs):
96         """Create the widget, passing ``*args`` and ``**kwargs`` to the superclass constructor."""
97         super().__init__(*args, **kwargs)
98
99         self.point_i: tuple[float, float] = (1., 0.)
100        self.point_j: tuple[float, float] = (0., 1.)
101
102        self.colour_i = QColor(37, 244, 15)
103        self.colour_j = QColor(8, 8, 216)
104
105        self.width_vector_line = 1
106        self.width_transformed_grid = 0.6
107
108        def transform_by_matrix(self, matrix: MatrixType) -> None:
109            """Transform the plane by the given matrix."""
110            self.point_i = (matrix[0][0], matrix[1][0])
111            self.point_j = (matrix[0][1], matrix[1][1])
112            self.update()

```

I also created a `draw_transformed_grid()` method which gets called in `paintEvent()`.

```

# 37e7c208a33d7cbbc8e0bb6c94cd889e2918c605
# src/lintrans/gui/plots/plot_widget.py

122 def draw_transformed_grid(self, painter: QPainter) -> None:
123     """Draw the transformed version of the grid, given by the unit vectors."""
124     # Draw the unit vectors
125     painter.setPen(QPen(self.colour_i, self.width_vector_line))
126     painter.drawLine(*self.origin, *self.trans_coords(*self.point_i))
127     painter.setPen(QPen(self.colour_j, self.width_vector_line))
128     painter.drawLine(*self.origin, *self.trans_coords(*self.point_j))

```

I then changed the `render_expression()` method in `LintransMainWindow` to call this new `transform_by_matrix()` method.

```

# 37e7c208a33d7cbbc8e0bb6c94cd889e2918c605
# src/lintrans/gui/main_window.py

229 def render_expression(self) -> None:
230     """Render the expression in the input box, and then clear the box."""
231     self.plot.transform_by_matrix(
232         self.matrix_wrapper.evaluate_expression(
233             self.lineedit_expression_box.text()
234         )
235     )

```

Testing this new code shows that it works well.

Figure 3.5: Basis vectors drawn for a  $45^\circ$  rotation

### 3.3.4 Drawing the transformed grid

After drawing the basis vectors, I wanted to draw the transformed version of the grid. I first created a `grid_corner()` utility method to return the grid coordinates of the top right corner of the canvas. This allows me to find the bounding box in which to draw the grid lines.

```
# 2ade98ac28d1c3f6691e4afa819142a3ab8e9fd9
# src/lintrans/gui/plots/plot_widget.py

64     def grid_corner(self) -> tuple[float, float]:
65         """Return the grid coords of the top right corner."""
66         return self.width() / (2 * self.grid_spacing), self.height() / (2 * self.grid_spacing)
```

I then created a `draw_parallel_lines()` method that would fill the bounding box with a set of lines parallel to a given vector with spacing defined by the intersection with a given point.

```
# 2ade98ac28d1c3f6691e4afa819142a3ab8e9fd9
# src/lintrans/gui/plots/plot_widget.py

126     def draw_parallel_lines(self, painter: QPainter, vector: tuple[float, float], point: tuple[float, float]) ->
127         ↪ None:
128         """Draw a set of grid lines parallel to `vector` intersecting `point`."""
129         max_x, max_y = self.grid_corner()
130         vector_x, vector_y = vector
131         point_x, point_y = point
132
133         if vector_x == 0:
134             painter.drawLine(self.trans_x(0), 0, self.trans_x(0), self.height())
135
136         for i in range(int(max_x / point_x)):
137             painter.drawLine(
138                 self.trans_x((i + 1) * point_x),
139                 0,
140                 self.trans_x((i + 1) * point_x),
141                 self.height()
142             )
143             painter.drawLine(
144                 self.trans_x(-1 * (i + 1) * point_x),
```

```

144         0,
145         self.trans_x(-1 * (i + 1) * point_x),
146         self.height()
147     )
148
149     elif vector_y == 0:
150         painter.drawLine(0, self.trans_y(0), self.width(), self.trans_y(0))
151
152     for i in range(int(max_y / point_y)):
153         painter.drawLine(
154             0,
155             self.trans_y((i + 1) * point_y),
156             self.width(),
157             self.trans_y((i + 1) * point_y)
158         )
159         painter.drawLine(
160             0,
161             self.trans_y(-1 * (i + 1) * point_y),
162             self.width(),
163             self.trans_y(-1 * (i + 1) * point_y)
164         )

```

I then called this method from `draw_transformed_grid()`.

```

# 2ade98ac28d1c3f6691e4afa819142a3ab8e9fd9
# src/lintrans/gui/plots/plot_widget.py

166 def draw_transformed_grid(self, painter: QPainter) -> None:
167     """Draw the transformed version of the grid, given by the unit vectors."""
168     # Draw the unit vectors
169     painter.setPen(QPen(self.colour_i, self.width_vector_line))
170     painter.drawLine(*self.origin, *self.trans_coords(*self.point_i))
171     painter.setPen(QPen(self.colour_j, self.width_vector_line))
172     painter.drawLine(*self.origin, *self.trans_coords(*self.point_j))
173
174     # Draw all the parallel lines
175     painter.setPen(QPen(self.colour_i, self.width_transformed_grid))
176     self.draw_parallel_lines(painter, self.point_i, self.point_j)
177     painter.setPen(QPen(self.colour_j, self.width_transformed_grid))
178     self.draw_parallel_lines(painter, self.point_j, self.point_i)

```

This worked quite well when the matrix involved no rotation, as seen in Figure ??, but this didn't work with rotation. When trying `'rot(45)'` for example, it looked the same as in Figure 3.5.

Also, the vectors aren't particularly clear. They'd be much better with arrowheads on their tips, but this is just a prototype. The arrowheads will come later.

My next step was to make the transformed grid lines work with rotations.

Figure 3.6: Parallel lines being drawn for matrix  $1.2\mathbf{I}$

```

# 7dfe1e24729562501e2fd88a839dca6b653a3375
# src/lintrans/gui/plots/plot_widget.py

126 def draw_parallel_lines(self, painter: QPainter, vector: tuple[float, float], point: tuple[float, float]) -> None:
127     """Draw a set of grid lines parallel to `vector` intersecting `point`."""
128     max_x, max_y = self.grid_corner()
129     vector_x, vector_y = vector
130     point_x, point_y = point

```

```
131
132     print(max_x, max_y, vector_x, vector_y, point_x, point_y)
133
134     # We want to use y = mx + c but m = y / x and if either of those are 0, then this
135     # equation is harder to work with, so we deal with these edge cases first
136     if abs(vector_x) < 1e-12 and abs(vector_y) < 1e-12:
137         # If both components of the vector are practically 0, then we can't render any grid lines
138         return
139
140     elif abs(vector_x) < 1e-12:
141         painter.drawLine(self.trans_x(0), 0, self.trans_x(0), self.height())
142
143         for i in range(abs(int(max_x / point_x))):
144             painter.drawLine(
145                 self.trans_x((i + 1) * point_x),
146                 0,
147                 self.trans_x((i + 1) * point_x),
148                 self.height()
149             )
150             painter.drawLine(
151                 self.trans_x(-1 * (i + 1) * point_x),
152                 0,
153                 self.trans_x(-1 * (i + 1) * point_x),
154                 self.height()
155             )
156
157     elif abs(vector_y) < 1e-12:

166             )
167             painter.drawLine(
168                 0,
169                 self.trans_y(-1 * (i + 1) * point_y),
170                 self.width(),
171                 self.trans_y(-1 * (i + 1) * point_y)
172             )
173
174     else: # If the line is not horizontal or vertical, then we can use y = mx + c
175         m = vector_y / vector_x
176         c = point_y - m * point_x
177
178         # For c = 0
179         painter.drawLine(
180             *self.trans_coords(
181                 -1 * max_x,
182                 m * -1 * max_x
183             ),
184             *self.trans_coords(
185                 max_x,
186                 m * max_x
187             )
188         )
189
190         # Count up how many multiples of c we can have without wasting time rendering lines off screen
191         multiples_of_c: int = 0
192         ii: int = 1
193         while True:
194             y1 = m * max_x + ii * c
195             y2 = -1 * m * max_x + ii * c
196
197             if y1 < max_y or y2 < max_y:
198                 multiples_of_c += 1
199                 ii += 1
200
201         else:
202             break
203
```

```

204     # Once we know how many lines we can draw, we just draw them all
205     for i in range(1, multiples_of_c + 1):
206         painter.drawLine(
207             *self.trans_coords(
208                 -1 * max_x,
209                 m * -1 * max_x + i * c
210             ),
211             *self.trans_coords(
212                 max_x,
213                 m * max_x + i * c
214             )
215         )
216         painter.drawLine(
217             *self.trans_coords(
218                 -1 * max_x,
219                 m * -1 * max_x - i * c
220             ),
221             *self.trans_coords(
222                 max_x,
223                 m * max_x - i * c
224             )
225         )

```

This code checks if  $x$  or  $y$  is zero<sup>10</sup> and if they're not, then we have to use the standard straight line equation  $y = mx + c$  to create parallel lines. We find our value of  $m$  and then iterate through all the values of  $c$  that keep the line within the bounding box.

Figure 3.7: An example of a 20° rotation

There are some serious logical errors in this code. It works fine for things like '3rot(45)' or '0.5rot(20)', but something like 'rot(115)' will leave the program hanging indefinitely.

In fact, this code only works for rotations between 0° and 90°, and will hang forever when given a matrix like  $\begin{pmatrix} 12 & 4 \\ -2 & 3 \end{pmatrix}$ , because it's just not very good.

I will fix these issues in the future, but it works somewhat decently, so I decided to do animation next, because that sounded more fun.

### 3.3.5 Implementing animation

Now that I had a very crude renderer, I could create a method to animate a matrix. Eventually I want to be able to apply a given matrix to the currently rendered scene and animate between them. However, I wanted to start simple by animating from the identity to the given matrix.

```

# 829a130af5aee9819bf0269c03ecfb20bec1a108
# src/lintrans/gui/main_window.py

238     def animate_expression(self) -> None:
239         """Animate the expression in the input box, and then clear the box."""
240         self.button_render.setEnabled(False)
241         self.button_animate.setEnabled(False)
242
243         matrix = self.matrix_wrapper.evaluate_expression(self.lineEdit_expression_box.text())
244         matrix_move = matrix - self.matrix_wrapper['I']
245         steps: int = 100
246
247         for i in range(0, steps + 1):

```

<sup>10</sup>We actually check if they're less than  $10^{-12}$  to allow for floating point errors

```

248     self.plot.visualize_matrix_transformation(
249         self.matrix_wrapper['I'] + (i / steps) * matrix_move
250     )
251
252     self.update()
253     self.repaint()
254
255     time.sleep(0.01)
256
257     self.button_render.setEnabled(False)
258     self.button_animate.setEnabled(False)

```

This code creates the `matrix_move` variable and adds scaled versions of it to the identity matrix and renders that each frame. It's simple, but it works well for this simple use case. Unfortunately, it's very hard to show off an animation in a PDF, since all these images are static. The git commit hashes are included in the code snippets if you want to clone the repo[2], checkout this commit, and run it yourself if you want.

### 3.3.6 Preserving determinants

Ignoring the obvious flaw with not being able to render transformations with a more than  $90^\circ$  rotation, the animations don't respect determinants. When rotating  $90^\circ$ , the determinant changes during the animation, even though we're going from a determinant 1 matrix (the identity) to another determinant 1 matrix. This is because we're just moving each vector to its new position in a straight line. I want to animate in a way that smoothly transitions the determinant.

Figure 3.8: What we would expect halfway through a  $90^\circ$  rotation

Figure 3.9: What we actually get halfway through a  $90^\circ$  rotation

In order to smoothly animate the determinant, I had to do some maths. I first defined the matrix **A** to be equivalent to the `matrix_move` variable from before - the target matrix minus the identity, scaled by the proportion. I then wanted to normalize **A** so that it had a determinant of 1 so that I could scale it up with the `proportion` variable through the animation.

I think I first tried just multiplying **A** by  $\frac{1}{\det(\mathbf{A})}$  but that didn't work, so I googled it. I found a post[12] on ResearchGate about the topic, and thanks to a very helpful comment from Jeffrey L Stuart, I learned that for a  $2 \times 2$  matrix **A** and a scalar  $c$ ,  $\det(c\mathbf{A}) = c^2 \det(\mathbf{A})$ .

I wanted a  $c$  such that  $\det(c\mathbf{A}) = 1$ . Therefore  $c = \frac{1}{\sqrt{|\det(\mathbf{A})|}}$ . I then defined matrix **B** to be  $c\mathbf{A}$ .

Then I wanted to scale this normalized matrix **B** to have the same determinant as the target matrix **T** using some scalar  $d$ . We know that  $\det(d\mathbf{B}) = d^2 \det(\mathbf{B}) = \det(\mathbf{T})$ . We can just rearrange to find  $d$

and get  $d = \sqrt{\left| \frac{\det(\mathbf{T})}{\det(\mathbf{B})} \right|}$ . But  $\mathbf{B}$  is defined so that  $\det(\mathbf{B}) = 1$ , so we can get  $d = \sqrt{|\det(\mathbf{T})|}$ .

However, we want to scale this over time with our proportion variable  $p$ , so our final scalar  $s = 1 + p \left( \sqrt{|\det(\mathbf{T})|} - 1 \right)$ . We define a matrix  $\mathbf{C} = s\mathbf{B}$  and render  $\mathbf{C}$  each frame. When in code form, this is the following:

```
# 6ff49450d8438ea2b2e7d2a97125dc518e648bc5
# src/lintrans/gui/main_window.py

245     # Get the target matrix and it's determinant
246     matrix_target = self.matrix_wrapper.evaluate_expression(self.lineedit_expression_box.text())
247     det_target = linalg.det(matrix_target)
248
249     identity = self.matrix_wrapper['I']
250     steps: int = 100
251
252     for i in range(0, steps + 1):
253         # This proportion is how far we are through the loop
254         proportion = i / steps
255
256         # matrix_a is the identity plus some part of the target, scaled by the proportion
257         # If we just used matrix_a, then things would animate, but the determinants would be weird
258         matrix_a = identity + proportion * (matrix_target - identity)
259
260         # So to fix the determinant problem, we get the determinant of matrix_a and use it to normalise
261         det_a = linalg.det(matrix_a)
262
263         # For a 2x2 matrix A and a scalar c, we know that det(cA) = c^2 det(A)
264         # We want B = cA such that det(B) = 1, so then we can scale it with the animation
265         # So we get c^2 det(A) = 1 => c = sqrt(1 / abs(det(A)))
266         # Then we scale A down to get a determinant of 1, and call that matrix_b
267         if det_a == 0:
268             c = 0
269         else:
270             c = np.sqrt(1 / abs(det_a))
271
272         matrix_b = c * matrix_a
273
274         # matrix_c is the final matrix that we transform by
275         # It's B, but we scale it up over time to have the target determinant
276
277         # We want some C = dB such that det(C) is some target determinant T
278         # det(dB) = d^2 det(B) = T => d = sqrt(abs(T / det(B)))
279         # But we defined B to have det 1, so we can ignore it there
280
281         # We're also subtracting 1 and multiplying by the proportion and then adding one
282         # This just scales the determinant along with the animation
283         scalar = 1 + proportion * (np.sqrt(abs(det_target)) - 1)
284
285         matrix_c = scalar * matrix_b
286
287         self.plot.visualize_matrix_transformation(matrix_c)
288
289         self.repaint()
290         time.sleep(0.01)
```

Unfortunately, the system I use to render matrices is still quite bad at its job. This makes it hard to test properly. But, transformations like `'2rot(90)'` work exactly as expected, which is very good.

## 3.4 Improving the GUI

### 3.4.1 Fixing rendering

Now that I had the basics of matrix visualization sorted, I wanted to make the GUI and UX better. My first step was overhauling the rendering code to make it actually work with rotations of more than  $90^\circ$ .

I narrowed down the issue with PyCharm's debugger and found that the loop in `VectorGridPlot.draw_parallel_lines()` was looping forever if it tried to do anything outside of the top right quadrant. To fix this, I decided to instead delegate this task of drawing a set of oblique lines to a separate method, and work on that instead.

```
# cf05e09e5ebb6ea7a96db8660d0d8de6b946490a
# src/lintrans/gui/plots/classes.py

203         else: # If the line is not horizontal or vertical, then we can use  $y = mx + c$ 
204             m = vector_y / vector_x
205             c = point_y - m * point_x
206
207             # For  $c = 0$ 
208             painter.drawLine(
209                 *self.trans_coords(
210                     -1 * max_x,
211                     m * -1 * max_x
212                 ),
213                 *self.trans_coords(
214                     max_x,
215                     m * max_x
216                 )
217             )
218
219             # We keep looping and increasing the multiple of  $c$  until we stop drawing lines on the canvas
220             multiple_of_c = 1
221             while self.draw_pair_of_oblique_lines(painter, m, multiple_of_c * c):
222                 multiple_of_c += 1
```

This separation of functionality made designing and debugging this part of the solution much easier. The `draw_pair_of_oblique_lines()` method looked like this:

```
# cf05e09e5ebb6ea7a96db8660d0d8de6b946490a
# src/lintrans/gui/plots/classes.py

224     def draw_pair_of_oblique_lines(self, painter: QPainter, m: float, c: float) -> bool:
225         """Draw a pair of oblique lines, using the equation  $y = mx + c$ .
226
227         This method just calls :meth:`draw_oblique_line` with ``c`` and ``-c``,
228         and returns True if either call returned True.
229
230         :param QPainter painter: The ``QPainter`` object to use for drawing the vectors and grid lines
231         :param float m: The gradient of the lines to draw
232         :param float c: The y-intercept of the lines to draw. We use the positive and negative versions
233         :returns bool: Whether we were able to draw any lines on the canvas
234         """
235         return any([
236             self.draw_oblique_line(painter, m, c),
237             self.draw_oblique_line(painter, m, -c)
238         ])
239
240     def draw_oblique_line(self, painter: QPainter, m: float, c: float) -> bool:
241         """Draw an oblique line, using the equation  $y = mx + c$ .
242
243         We only draw the part of the line that fits within the canvas, returning True if
244         we were able to draw a line within the boundaries, and False if we couldn't draw a line
245
246         :param QPainter painter: The ``QPainter`` object to use for drawing the vectors and grid lines
```

```

247 :param float m: The gradient of the line to draw
248 :param float c: The y-intercept of the line to draw
249 :returns bool: Whether we were able to draw a line on the canvas
250 """
251 max_x, max_y = self.grid_corner()
252
253 # These variable names are shortened for convenience
254 # myi is max_y_intersection, mmyi is minus_max_y_intersection, etc.
255 myi = (max_y - c) / m
256 mmyi = (-max_y - c) / m
257 mxi = max_x * m + c
258 mmxi = -max_x * m + c
259
260 # The inner list here is a list of coords, or None
261 # If an intersection fits within the bounds, then we keep its coord,
262 # else it is None, and then gets discarded from the points list
263 # By the end, points is a list of two coords, or an empty list
264 points: list[tuple[float, float]] = [
265     x for x in [
266         (myi, max_y) if -max_x < myi < max_x else None,
267         (mmyi, -max_y) if -max_x < mmyi < max_x else None,
268         (max_x, mxi) if -max_y < mxi < max_y else None,
269         (-max_x, mmxi) if -max_y < mmxi < max_y else None
270     ] if x is not None
271 ]
272
273 # If no intersections fit on the canvas
274 if len(points) < 2:
275     return False
276
277 # If we can, then draw the line
278 else:
279     painter.drawLine(
280         *self.trans_coords(*points[0]),
281         *self.trans_coords(*points[1])
282     )
283     return True

```

To illustrate what this code is doing, I'll use a diagram.

Figure 3.10: Two example lines and the viewport box

Figure 3.11: A demonstration of the new oblique lines system.

The red box represents the viewport of the GUI. The dashed lines represent the extensions of the red box. For a given line we want to draw, we first want to find where it intersects these orthogonal lines. Any oblique line will intersect each of these lines exactly once. This is what the myi, mmyi, mxi, and

`mmxi` variables represent. The value of `myi` is the  $x$  value where the line intersects the maximum  $y$  line, for example.

In the case of the blue line, all 4 intersection points are outside the bounds of the box, whereas the green line intersects with the box, as shown with the crosses. We use a list comprehension over a list of ternaries to get the `points` list. This list contains 0 or 2 coordinates, and we may or may not draw a line accordingly.

That's how the `draw_oblique_line()` method works, and the `draw_pair_of_oblique_lines()` method just calls it with positive and negative values of  $c$ .

### 3.4.2 Adding vector arrowheads

Figure 3.12: An example of a vector with the arrowheads highlighted in green

Now that I had a good renderer, I wanted to add arrowheads to the vectors to make them easier to see. They were already thicker than the gridlines, but adding arrowheads like in the `3blue1brown` series would make them much easier to see. Unfortunately, I couldn't work out how to do this.

I wanted a function that would take a coordinate, treat it as a unit vector, and draw lines at  $45^\circ$  angles at the tip. This wasn't how I was conceptualising the problem at the time and because of that, I couldn't work out how to solve this problem. I could create this  $45^\circ$  lines in the top right quadrant, but none of my possible solutions worked for any arbitrary point.

So I started googling and found a very nice algorithm on [csharpshelper.com](http://csharpshelper.com)<sup>11</sup>, which I adapted for Python.

```
# 5373b1ad8040f6726147cccea523c0570251cf67
# src/lintrans/gui/plots/widgets.py
```

```
52 def draw_arrowhead_away_from_origin(self, painter: QPainter, point: tuple[float, float]) -> None:
53     """Draw an arrowhead at ``point``, pointing away from the origin.
54
55     :param QPainter painter: The ``QPainter`` object to use to draw the arrowheads with
56     :param point: The point to draw the arrowhead at, given in grid coords
57     :type point: tuple[float, float]
58     """
59     # This algorithm was adapted from a C# algorithm found at
60     # http://csharpshelper.com/blog/2014/12/draw-lines-with-arrowheads-in-c/
61
62     # Get the x and y coords of the point, and then normalize them
63     # We have to normalize them, or else the size of the arrowhead will
64     # scale with the distance of the point from the origin
65     x, y = point
66     nx = x / np.sqrt(x * x + y * y)
67     ny = y / np.sqrt(x * x + y * y)
68
69     # We choose a length and do some magic to find the steps in the x and y directions
70     length = 0.15
71     dx = length * (-nx - ny)
72     dy = length * (nx - ny)
73
74     # Then we just plot those lines
75     painter.drawLine(*self.trans_coords(x, y), *self.trans_coords(x + dx, y + dy))
76     painter.drawLine(*self.trans_coords(x, y), *self.trans_coords(x - dy, y + dx))
```

<sup>11</sup>This website is currently being rewritten and this arrowheads tutorial is listed as 'not rebuilt' on <http://csharpshelper.com>

```

77
78 def draw_vector_arrowheads(self, painter: QPainter) -> None:
79     """Draw arrowheads at the tips of the basis vectors.
80
81     :param QPainter painter: The ``QPainter`` object to use to draw the arrowheads with
82     """
83     painter.setPen(QPen(self.colour_i, self.width_vector_line))
84     self.draw_arrowhead_away_from_origin(painter, self.point_i)
85     painter.setPen(QPen(self.colour_j, self.width_vector_line))
86     self.draw_arrowhead_away_from_origin(painter, self.point_j)

```

As the comments suggest, we get the  $x$  and  $y$  components of the normalised vector, and then do some magic with a chosen length and get some distance values, and then draw those lines. I don't really understand how this code works, but I'm happy that it does. All we have to do is call `draw_vector_arrowheads()` from `paintEvent()`.

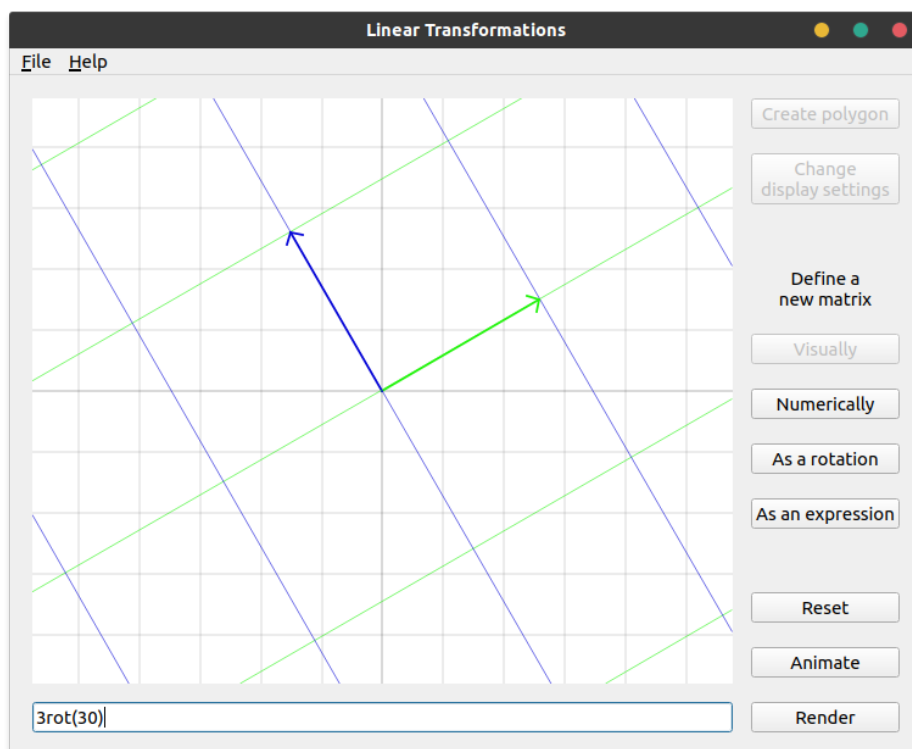

Figure 3.13: An example of the  $i$  and  $j$  vectors with arrowheads

### 3.4.3 Implementing zoom

The next thing I wanted to do was add the ability to zoom in and out of the viewport, and I wanted a button to reset the zoom level as well. I added a `default_grid_spacing` class attribute in `BackgroundPlot` and used that as the `grid_spacing` instance attribute in `__init__()`.

```

# d944e86e1d0fdc2c4be4d63479bc6bc3a31568ef
# src/lintrans/gui/plots/classes.py

27 default_grid_spacing: int = 50
28
29 def __init__(self, *args, **kwargs):
30     """Create the widget and setup backend stuff for rendering.
31
32     .. note:: ``*args`` and ``**kwargs`` are passed the superclass constructor (``QWidget``).
33     """

```

```

34     super().__init__(*args, **kwargs)
35
36     self.setAutoFillBackground(True)
37
38     # Set the background to white
39     palette = self.palette()
40     palette.setColor(self.backgroundRole(), Qt.white)
41     self.setPalette(palette)
42
43     # Set the grid colour to grey and the axes colour to black
44     self.colour_background_grid = QColor(128, 128, 128)
45     self.colour_background_axes = QColor(0, 0, 0)
46
47     self.grid_spacing = BackgroundPlot.default_grid_spacing

```

The reset button in `LintransMainWindow` simply sets `plot.grid_spacing` to the default.

To actually allow for zooming, I had to implement the `wheelEvent()` method in `BackgroundPlot` to listen for mouse wheel events. After reading through the docs for the `QWheelEvent` class[18], I learned how to handle this event.

```

# d944e86e1d0fdc2c4be4d63479bc6bc3a31568ef
# src/lintrans/gui/plots/classes.py

119 def wheelEvent(self, event: QWheelEvent) -> None:
120     """Handle a ``QWheelEvent`` by zooming in or out of the grid."""
121     # angleDelta() returns a number of units equal to 8 times the number of degrees rotated
122     degrees = event.angleDelta() / 8
123
124     if degrees is not None:
125         self.grid_spacing = max(1, self.grid_spacing + degrees.y())
126
127     event.accept()
128     self.update()

```

All we do is get the amount that the user scrolled and add that to the current spacing, taking the max with 1, which acts as a minimum grid spacing. We need to use `degrees.y()` on line 125 because Qt5 allows for mice that can scroll in the  $x$  and  $y$  directions, and we only want the  $y$  component. Line 127 marks the event as accepted so that the parent widget doesn't try to act on it.

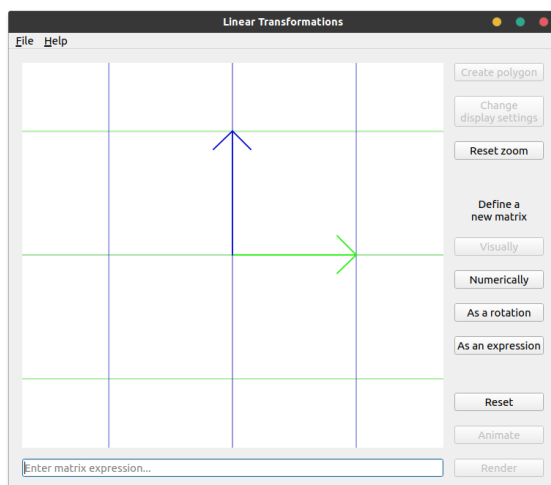

Figure 3.14: The GUI zoomed in a bit

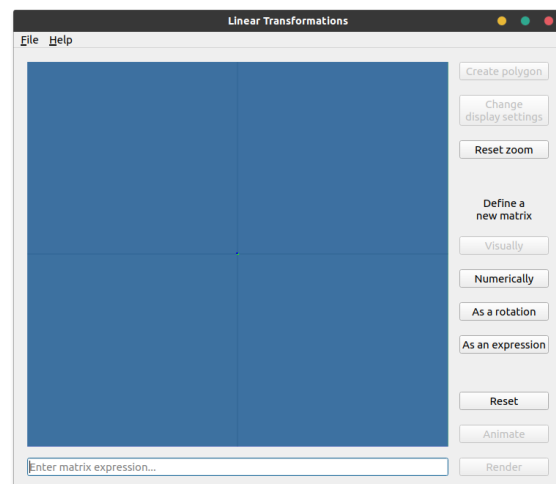

Figure 3.15: The GUI zoomed out as far as possible

There are two things I don't like here. Firstly, the minimum grid spacing is too small. The user can zoom out too far. Secondly, the arrowheads are too big in figure 3.14.

The first problem is minor and won't be fixed for quite a while, but I fixed the second problem quite quickly.

We want the arrowhead length to not just be 0.15, but to scale with the zoom level (the ratio between default grid spacing and current spacing).

This creates a slight issue when zoomed out all the way, because the arrowheads are then far larger than the vectors themselves, so we take the minimum of the scaled length and the vector length.

I factored out the default arrowhead length into the `arrowhead_length` instance attribute and initialize it in `__init__()`.

```
# 3d19a003368ae992ebb60049685bb04fde0836b5
# src/lintrans/gui/plots/widgets.py

68     vector_length = np.sqrt(x * x + y * y)
69     nx = x / vector_length
70     ny = y / vector_length
71
72     # We choose a length and find the steps in the x and y directions
73     length = min(
74         self.arrowhead_length * self.default_grid_spacing / self.grid_spacing,
75         vector_length
76     )
```

This code results in arrowheads that stay the same length unless the user is zoomed out basically as far as possible.

Figure 3.16: The arrowheads adjusted for zoom level

### 3.4.4 Animation blocks zooming

The biggest problem with this new zoom feature is that when animating between matrices, the user is unable to zoom. This is because when `LintransMainWindow.animate_expression()` is called, it uses Python's standard library `time.sleep()` function to delay each frame, which prevents Qt from handling user interaction while we're animating. This was a problem.

I did some googling and found a helpful post on StackOverflow[9] that gave me a nice solution. The user `ekhumoro` used the functions `QApplication.processEvents()` and `QThread.msleep()` to solve the problem, and I used these functions in my own app, with much success.

After reading 'The Event System' in the Qt5 documentation[24], I learned that Qt5 uses an event loop, a lot like JavaScript. This means that events are scheduled to be executed on the next pass of the event loop. I also read the documentation for the `repaint()` and `update()` methods on the `QWidget` class[20, 21] and decided that it would be better to just queue a repaint by calling `update()` on the plot rather than immediately repaint with `repaint()`, and then call `QApplication.processEvents()` to process the pending events on the main thread. This is a nicer way of repainting, which reduces potential flickering issues, and using `QThread.msleep()` allows for asynchronous processing and therefore non-blocking animation.

### 3.4.5 Rank 1 transformations

The rank of a matrix is the dimension of its column space. This is the dimension of the span of its columns, which is to say the dimension of the output space. The rank of a matrix must be less than or equal to the dimension of the matrix, so we only need to worry about ranks 0, 1, and 2. There is only one rank 0 matrix, which is the **0** matrix itself. I've already covered this case by just not drawing any transformed grid lines.

Rank 2 matrices encompass most 2D matrices, and I've already covered this case in §3.3.4 and §3.4.1. A rank 1 matrix collapses all of 2D space onto a single line, so for this type of matrix, we should just draw this line.

This code is in `VectorGridPlot.draw_parallel_lines()`. We assemble the matrix  $\begin{pmatrix} \text{vector\_x} & \text{point\_x} \\ \text{vector\_y} & \text{point\_y} \end{pmatrix}$  (which is actually the matrix used to create the transformation we're trying to render lines for) and use this matrix to check determinant and rank.

```
# 677b38c87bb6722b16aaf35058cf3cef66e43c21
# src/lintrans/gui/plots/classes.py

177     # If the determinant is 0
178     if abs(vector_x * point_y - vector_y * point_x) < 1e-12:
179         rank = np.linalg.matrix_rank(
180             np.array([
181                 [vector_x, point_x],
182                 [vector_y, point_y]
183             ])
184         )
185
186     # If the matrix is rank 1, then we can draw the column space line
187     if rank == 1:
188         self.draw_oblique_line(painter, vector_y / vector_x, 0)
189
190     # If the rank is 0, then we don't draw any lines
191     else:
192         return
```

Additionally, there was a bug with animating these determinant 0 matrices, since we try to scale the determinant through the animation, as documented in §3.3.6, but when the determinant is 0, this causes

issues. To fix this, we just check the `det_target` variable in `LintransMainWindow.animate_expression` and if it's 0, we use the non-scaled version of the matrix.

```
# b889b686d997c2b64124bee786bccba3fc4f6b08
# src/lintrans/gui/main_window.py

307         # If we're animating towards a det 0 matrix, then we don't want to scale the
308         # determinant with the animation, because this makes the process not work
309         # I'm doing this here rather than wrapping the whole animation logic in an
310         # if block mainly because this looks nicer than an extra level of indentation
311         # The extra processing cost is negligible thanks to NumPy's optimizations
312         if det_target == 0:
313             matrix_c = matrix_a
314         else:
315             matrix_c = scalar * matrix_b
```

### 3.4.6 Matrices that are too big

One of my friends was playing around with the prototype and she discovered a bug. When trying to render really big matrices, we can get errors like `'OverflowError: argument 3 overflowed: value must be in the range -2147483648 to 2147483647'` because PyQt5 is a wrapper over Qt5, which is a C++ library that uses the C++ `int` type for the `painter.drawLine()` call. This type is a 32-bit integer. Python can store integers of arbitrary precision, but when PyQt5 calls the underlying C++ library code, this gets cast to a C++ `int` and we can get an `OverflowError`.

This isn't a problem with the gridlines, because we only draw them inside the viewport, as discussed in §3.4.1, and these calculations all happen in Python, so integer precision is not a concern. However, when drawing the basis vectors, we just draw them directly, so we'll have to check that they're within the limit.

I'd previously created a `LintransMainWindow.show_error_message()` method for telling the user when they try to take the inverse of a singular matrix<sup>12</sup>.

```
# 0f699dd95b6431e95b2311dcb03e7af49c19613f
# src/lintrans/gui/main_window.py

378     def show_error_message(self, title: str, text: str, info: str | None = None) -> None:
379         """Show an error message in a dialog box.
380
381         :param str title: The window title of the dialog box
382         :param str text: The simple error message
383         :param info: The more informative error message
384         :type info: Optional[str]
385         """
386         dialog = QMessageBox(self)
387         dialog.setIcon(QMessageBox.Critical)
388         dialog.setWindowTitle(title)
389         dialog.setText(text)
390
391         if info is not None:
392             dialog.setInformativeText(info)
393
394         dialog.open()
395
396         dialog.finished.connect(self.update_render_buttons)
```

I then created the `is_matrix_too_big()` method to just check that the elements of the matrix are within the desired bounds. If it returns `True` when we try to render or animate, then we call `show_error_message()`.

```
# 4682a7b225747cfd77aca0fe3abccdd1397b7c5dd
# src/lintrans/gui/main_window.py
```

<sup>12</sup>This commit didn't get a standalone section in this write-up because it was so small

```

407     def is_matrix_too_big(self, matrix: MatrixType) -> bool:
408         """Check if the given matrix will actually fit onto the canvas.
409
410         Convert the elements of the matrix to canvas coords and make sure they fit within Qt's 32-bit integer limit.
411
412         :param MatrixType matrix: The matrix to check
413         :returns bool: Whether the matrix fits on the canvas
414         """
415         coords: list[tuple[int, int]] = [self.plot.trans_coords(*vector) for vector in matrix.T]
416
417         for x, y in coords:
418             if not (-2147483648 <= x <= 2147483647 and -2147483648 <= y <= 2147483647):
419                 return True
420
421         return False

```

### 3.4.7 Creating the DefineVisuallyDialog

Next, I wanted to allow the user to define a matrix visually by dragging the basis vectors. To do this, I obviously needed a new DefineDialog subclass for it.

```

# 16ca0229aab73b3f4a8fe752dee3608f3ed6ead5
# src/lintrans/gui/dialogs/define_new_matrix.py

135 class DefineVisuallyDialog(DefineDialog):
136     """The dialog class that allows the user to define a matrix visually."""
137
138     def __init__(self, matrix_wrapper: MatrixWrapper, *args, **kwargs):
139         """Create the widgets and layout of the dialog.
140
141         :param MatrixWrapper matrix_wrapper: The MatrixWrapper that this dialog will mutate
142         """
143         super().__init__(matrix_wrapper, *args, **kwargs)
144
145         self.setMinimumSize(500, 450)
146
147         # === Create the widgets
148
149         self.combobox_letter.activated.connect(self.show_matrix)
150
151         self.plot = DefineVisuallyWidget(self)
152
153         # === Arrange the widgets
154
155         self.hlay_definition.addWidget(self.plot)
156         self.hlay_definition.setStretchFactor(self.plot, 1)
157
158         self.vlay_all = QVBoxLayout()
159         self.vlay_all.setSpacing(20)
160         self.vlay_all.addLayout(self.hlay_definition)
161         self.vlay_all.addLayout(self.hlay_buttons)
162
163         self.setLayout(self.vlay_all)
164
165         # We load the default matrix A into the plot
166         self.show_matrix(0)
167
168         # We also enable the confirm button, because any visually defined matrix is valid
169         self.button_confirm.setEnabled(True)
170
171     def update_confirm_button(self) -> None:
172         """Enable the confirm button.
173
174         .. note::
175             The confirm button is always enabled in this dialog and this method is never actually used,
176             so it's got an empty body. It's only here because we need to implement the abstract method.
177         """
178

```

```

179     def show_matrix(self, index: int) -> None:
180         """Show the selected matrix on the plot. If the matrix is None, show the identity."""
181         matrix = self.matrix_wrapper[ALPHABET_NO_I[index]]
182
183         if matrix is None:
184             matrix = self.matrix_wrapper['I']
185
186         self.plot.visualize_matrix_transformation(matrix)
187         self.plot.update()
188
189     def confirm_matrix(self) -> None:

```

This DefineVisuallyDialog class just implements the normal methods needed for a DefineDialog and has a plot attribute to handle drawing graphics and handling mouse movement. After creating the DefineVisuallyWidget as a skeleton and doing some more research in the Qt5 docs[19], I renamed the trans\_coords() methods to canvas\_coords() to make the intent more clear, and created a grid\_coords() method.

```

# 417aea6555029b049c470faff18df29f064f6101
# src/lintrans/gui/plots/classes.py

85     def grid_coords(self, x: int, y: int) -> tuple[float, float]:
86         """Convert a coordinate from canvas coords to grid coords.
87
88         :param int x: The x component of the canvas coordinate
89         :param int y: The y component of the canvas coordinate
90         :returns: The resultant grid coordinates
91         :rtype: tuple[float, float]
92         """
93         # We get the maximum grid coords and convert them into canvas coords
94         return (x - self.canvas_origin[0]) / self.grid_spacing, (-y + self.canvas_origin[1]) / self.grid_spacing

```

I then needed to implement the methods to handle mouse movement in the DefineVisuallyWidget class. Thankfully, Ross Wilson, the person who helped me learn about the QWidget.paintEvent() method in §3.3.1, also wrote an example of draggable points[5]. In my post, I had explained that I needed draggable points on my canvas, and Ross was helpful enough to create an example in their own time. I probably could've worked it out myself eventually, but this example allowed me to learn a lot quicker.

```

# 417aea6555029b049c470faff18df29f064f6101
# src/lintrans/gui/plots/widgets.py

56 class DefineVisuallyWidget(VisualizeTransformationWidget):
57     """This class is the widget that allows the user to visually define a matrix.
58
59     This is just the widget itself. If you want the dialog, use
60     :class:`lintrans.gui.dialogs.define_new_matrix.DefineVisuallyDialog`.
61     """
62
63     def __init__(self, *args, **kwargs):
64         """Create the widget and enable mouse tracking. ``*args`` and ``**kwargs`` are passed to ``super()``."""
65         super().__init__(*args, **kwargs)
66
67         # self.setMouseTracking(True)
68         self.dragged_point: tuple[float, float] | None = None
69
70         # This is the distance that the cursor needs to be from the point to drag it
71         self.epsilon: int = 5
72
73     def mousePressEvent(self, event: QMouseEvent) -> None:
74         """Handle a QMouseEvent when the user pressed a button."""
75         mx = event.x()
76         my = event.y()
77         button = event.button()
78
79         if button != Qt.LeftButton:

```

```

80         event.ignore()
81         return
82
83     for point in (self.point_i, self.point_j):
84         px, py = self.canvas_coords(*point)
85         if abs(px - mx) <= self.epsilon and abs(py - my) <= self.epsilon:
86             self.dragged_point = point[0], point[1]
87
88     event.accept()
89
90     def mouseReleaseEvent(self, event: QMouseEvent) -> None:
91         """Handle a QMouseEvent when the user release a button."""
92         if event.button() == Qt.LeftButton:
93             self.dragged_point = None
94             event.accept()
95         else:
96             event.ignore()
97
98     def mouseMoveEvent(self, event: QMouseEvent) -> None:
99         """Handle the mouse moving on the canvas."""
100         mx = event.x()
101         my = event.y()
102
103         if self.dragged_point is not None:
104             x, y = self.grid_coords(mx, my)
105
106             if self.dragged_point == self.point_i:
107                 self.point_i = x, y
108
109             elif self.dragged_point == self.point_j:
110                 self.point_j = x, y
111
112             self.dragged_point = x, y
113
114             self.update()
115
116             print(self.dragged_point)
117             print(self.point_i, self.point_j)
118
119         event.accept()
120
121     event.ignore()

```

This snippet has the line `'self.setMouseTracking(True)'` commented out. This line was in the example, but it turns out that I don't want it. Mouse tracking means that a widget will receive a `QMouseEvent` every time the mouse moves. But if it's disabled (the default), then the widget will only receive a `QMouseEvent` for mouse movement when a button is held down at the same time.

I've also left in some print statements on lines 116 and 117. These small oversights are there because I just forgot to remove them before I committed these changes. They were removed 3 commits later.

### 3.4.8 Fixing a division by zero bug

When drawing the rank line for a determinant 0, rank 1 matrix, we can encounter a division by zero error. I'm sure this originally manifested in a crash with a `ZeroDivisionError` at runtime, but now I can only get a `RuntimeWarning` when running the old code from commit `16ca0229aab73b3f4a8fe752dee3608f3ed6ead5`.

Whether it crashes or just warns the user, there is a division by zero bug when trying to render  $\begin{pmatrix} k & 0 \\ 0 & 0 \end{pmatrix}$  or  $\begin{pmatrix} 0 & 0 \\ 0 & k \end{pmatrix}$ . To fix this, I just handled those cases separately in `VectorGridPlot.draw_parallel_lines()`.

```

# 40bee6461d477a5c767ed132359cd511c0051e3b
# src/lintrans/gui/plots/classes.py

```

```
196     # If the matrix is rank 1, then we can draw the column space line
197     if rank == 1:
198         if abs(vector_x) < 1e-12:
199             painter.drawLine(self.width() // 2, 0, self.width() // 2, self.height())
200         elif abs(vector_y) < 1e-12:
201             painter.drawLine(0, self.height() // 2, self.width(), self.height() // 2)
202         else:
203             self.draw_oblique_line(painter, vector_y / vector_x, 0)
204
205     # If the rank is 0, then we don't draw any lines
206     else:
207         return
```
