1 Analysis

One of the topics in the A Level Further Maths course is linear transformations, as represented by matrices. This is a topic all about how vectors move and get transformed in the plane. It's a topic that lends itself exceedingly well to visualization, but students often find it hard to visualize this themselves, and there is a considerable lack of good tools to provide visual intuition on the subject. There is the YouTube series *Essence of Linear Algebra* by 3blue1brown[1], which is excellent, but I couldn't find any good interactive visualizations.

My solution is to develop a desktop application that will allow the user to define 2×2 matrices and view these matrices and compositions thereof as linear transformations of a 2D plane. This will give students a way to get to grips with linear transformations in a more hands-on way, and will give teachers the ability to easily and visually show concepts like the determinant and invariant lines.

1.1 Computational Approach

This solution is particularly well suited to a computational approach since it is entirely focussed on visualizing transformations, which require complex mathematics to properly display. It will also have lots of settings to allow the user to configure aspects of the visualization. As previously mentioned, visualizing transformations in one's own head is difficult, so a piece of software to do it would be very valuable to teachers and learners, but current solutions are considerably lacking.

My solution will make use of abstraction by allowing the user to define a set of matrices which they can use in expressions. This allows them to use a matrix multiple times and they don't have to keep track of any of the numbers. All the actual processing and mathematics happens behind the scenes and the user never has to worry about it - they just compose their defined matrices into transformations. This abstraction allows the user to focus on exploring the transformations themselves without having to do any actual computations. This will make learning the subject much easier, as they will able to gain a visual intuition for linear transformations without worrying about computation until after they've built up that intuition.

I will also employ decomposition and modularization by breaking the project down into many smaller parts, such as one module to keep track of defined matrices, one module to validate and parse matrix expressions, one module for the main GUI, as well as sub-modules for the widgets and dialog boxes, etc. This decomposition allows for simpler project design, easier code maintenance (since module coupling is kept to a minimum, so bugs are isolated in their modules), inheritance of classes to reduce code repetition, and unit testing to inform development. I also intend this unit testing to be automated using GitHub Actions.

Selection will also be used widely in the application. The GUI will provide many settings for visualization, and these settings will need to be checked when rendering the transformation. For example, the user will have the option to render the determinant, so I will need to check this setting on every render cycle and only render the determinant parallelogram if the user has enabled that option. The app will have many options for visualization, which will be useful in learning, but if all these options were being rendered at the same time, then there would be too much information for the user to properly process, so I will let the user configure these display options to their liking and only render the things they want to be rendered.

Validation will also be prevalent because the matrix expressions will need to follow a strict format, which will be validated. The buttons to render and animate the matrix will only be clickable when the given expression is valid, so I will need to check this and update the buttons every time the text in the text box is changed. I will also need to parse matrix expressions so that I can evaluate them properly. All this validation ensures that crashes due to malformed input are practically impossible, and makes the user's life easier since they don't need to worry about if their input is in the right format - the app will tell them.

I will also make use of iteration, primarily in animation. I will have to re-calculate positions and

values to render everything for every frame of the animation and this will likely be done with a simple for loop. A for loop will allow me to just loop over every frame and use the counter variable as a way to measure how far through the animation we are on each frame. This is preferable to a while loop, since that would require me to keep track of which frame we're on with a separate variable.

Centre number: 123456

Finally, the core of the application is visualization, so that will definitely be used a lot. I will have to calculate positions of points and lines based on given matrices, and when animating, I will also have to calculate these matrices based on the current frame. Then I will have to use the rendering capabilities of the GUI framework that I choose to render these calculated points and lines onto a widget, which will form the viewport of the main GUI. I may also have to convert between coordinate systems. I will have the origin in the middle with positive x going to the right and positive y going up, but I may need to convert that to standard computer graphics coordinates with the origin in the top left, positive x going to the right, and positive y going down. This visualization of linear transformations is the core component of the app and is the primary feature, so it is incredibly important.

1.2 Stakeholders

Stakeholders for my app include A Level Further Maths students and teachers, who learn and teach linear transformations respectively. They will be able to provide useful input as to what they would like to see in the app, and they can provide feedback on what they like and what I can add or improve. I already know from experience that linear transformations are tricky to visualize and a computer-based visualization would be useful. My stakeholders agreed with this. Many teachers said that a desktop app that could render and animate linear transformations would be useful in a classroom environment and students said that it would be helpful to have something that they could play around with at home and use to get to grips with matrices and linear transformations.

Some teachers also suggested that it would be useful to have an option to save and load sets of matrices. This would allow them to have a single save file containing some matrices, and then just load this file to use for demonstrations in the classroom. This would probably be quite easy to implement. I could just wrap all the relevant information into one object and use Python's pickle module to save the binary data to a file, and then load this data back into the app in a similar way.

My stakeholders agreed that being able to see incremental animation - where, for example, we apply matrix $\bf A$ to the current scene, pause, and then apply matrix $\bf B$ - would be beneficial. This would be a good demonstration of matrix multiplication being non-commutative. $\bf AB$ is not always equal to $\bf BA$. Being able to see this in terms of animating linear transformations would be good for learning.

They also agreed that a tutorial on using the software would be useful, so I plan to implement this through an online written tutorial hosted with GitHub Pages, and perhaps a video tutorial as well. This would make the app much easier to use for people who have never seen it before. It wouldn't be a lesson on the maths itself, just a guide on how to use the software.

1.3 Research on existing solutions

There are actually quite a few web apps designed to help visualize 2D linear transformations but many of them are hard to use and lacking many features.

1.3.1 MIT 'Matrix Vector' Mathlet

Arguably the best app that I found was an MIT 'Mathlet' - a simple web app designed to help visualize a maths concept. This one is called 'Matrix Vector' [2] and allows the user to drag an input vector around the plane and see the corresponding output vector, transformed by a matrix that the user can define, although this definition is finicky since it involves sliders rather than keyboard input.

This app fails in two crucial ways in my opinion. It doesn't show the basis vectors or let the user drag them around, and the user can only define and therefore visualize a single matrix at once. This second problem was common among every solution I found, so I won't mention it again, but it is a big issue in my opinion and my app will allow for multiple matrices. I like the idea of having a draggable input vector and rendering its output, so I will probably have this feature in my app, but I also want the ability to define multiple matrices and be able to drag the basis vectors to visually define a matrix. Being able to drag the basis vectors will help build intuition, so I think this would greatly benefit the app.

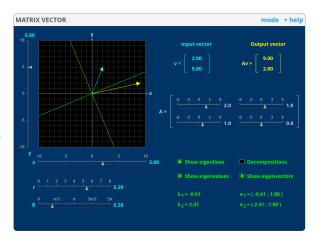

Figure 1: The MIT 'Matrix Vector' Mathlet

However, in the comments on this Mathlet, a user called 'David S. Bruce' suggested that the Mathlet should display the basis vectors, to which a user called 'hrm' (who I assume to be the 'H. Miller' to whom the copyright of the whole website is accredited) replied saying that this Mathlet is primarily focussed on eigenvectors, that it is perhaps badly named, and that displaying the basis vectors 'would make a good focus for a second Mathlet about 2×2 matrices'. This Mathlet does not exist. But I do like the idea of showing the eigenvectors and eigenlines, so I will definitely have that in my app. Showing the invariant lines or lack thereof will help with learning, since these are often hard to visualize.

1.3.2 Linear Transformation Visualizer

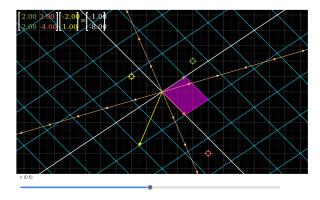

Figure 2: 'Linear Transformation Visualizer' halfway through an animation

Another web app that I found was one simply called 'Linear Transformation Visualizer' by Shad Sharma[3]. This one was similarly inspired by 3blue1brown's YouTube series. This app has the ability to render input and output vectors and eigenlines, but it can also render the determinant parallelogram; it allows the user to drag the basis vectors; and it has the option to snap vectors to the background grid, which is quite useful. It also implements a simple form of animation where the tips of the vectors move in straight lines from where they start to where they end, and the animation is controlled by dragging a slider labelled t. This isn't particularly intuitive.

I really like the vectors snapping to the grid, the input and output vectors, and rendering the determinant. This app also renders positive and negative determinants in different colours, which is really nice - I intend to use that idea in my own app, since it helps create understanding about negative determinants in terms of orientation changes. However, I think that the animation system here is flawed and not very easy to use. My animation will likely be a button, which just triggers an animation, rather than a slider. I also don't like the way vector dragging is handled. If you click anywhere on the grid, then the closest vector target (the final position of the target's associated vector) snaps to that location. I think it would be more intuitive to have to drag the vector from its current location to where you want it. This was also a problem with the MIT Mathlet.

1.3.3 Desmos app

One of the solutions I found was a Desmos app[4], which was quite hard to use and arguably over-complicated. Desmos is not designed for this kind of thing - it's designed to graph pure mathematical functions - and it shows here. However, this app brings some really interesting ideas to the table, mainly functions. This app allows you to define custom functions and view them before and after the transformation. This is achieved by treating the functions parametrically as the set of points (t, f(t)) and then transforming each coordinate by the given matrix to get a new coordinate.

Desmos does this for every point and then renders the resulting transformed function parametrically. This is a really interesting technique and idea, but I'm not going to use it in my app. I don't think arbitrary functions fit with the linearity of the whole app, and I don't think it's necessary. It's just overcomplicating things, and rendering it on a widget would be tricky, because I'd have to render every point myself, possibly using something like OpenGL. It's just not worth implementing.

Additionally, this Desmos app makes things quite hard to see. It's hard to tell where any of the vectors are - they just get lost in the sea of grid lines. This image also hides some of the extra information. For instance, this image doesn't

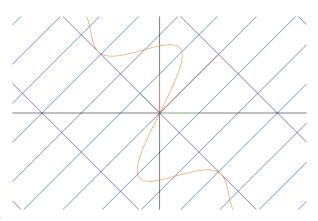

Figure 3: The Desmos app halfway through an animation, rendering $f(x) = \frac{\sin^2 x}{x}$ in orange

show the original function $f(x) = \frac{\sin^2 x}{x}$, only the transformed version. This app easily gets quite cluttered. I will give my vectors arrowheads to make them easily identifiable amongst the grid lines.

1.3.4 Visualizing Linear Transformations

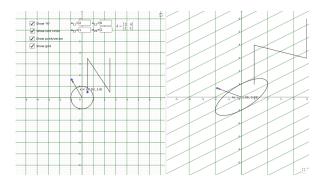

Figure 4: The GeoGebra applet rendering its default matrix

The last solution that I want to talk about is a GeoGebra applet simply titled 'Visualizing Linear Transformations'[5]. This applet has input and output vectors, original and transformed grid lines, a unit circle, and the letter N. It allows the user to define a matrix as 4 numbers and view the aforementioned N (which the user can translate to anywhere on the grid), the unit circle, the input/output vectors, and the grid lines. It also has the input vector snapping to integer coordinates, but that's a standard part of GeoGebra.

I've already talked about most of these features but the thing I wanted to talk about here is the N. I don't particularly want the letter N to be a prominent part of my own app, but I really like

the idea of being able to define a custom polygon and see how that polygon gets transformed by a given transformation. I think that would really help with building intuition and it shouldn't be too hard to implement.

1.4 Essential features

The primary aim of this application is to visualize linear transformations, so this will obviously be the centre of the app and an essential feature. I will have a widget which can render a background grid and a second version of the grid, transformed according to a user-defined matrix expression. This is necessary because it is the entire purpose of the app. It's designed to visualize linear transformations

and would be completely useless without this visual component. I will give the user the ability to render a custom matrix expression containing matrices they have previously defined, as well as reset the canvas to the default identity matrix transformation. This will obviously require an input box to enter the expression, a render button, a reset button, and various dialog boxes to define matrices in different ways. I want the user to be able to define a matrix as a set of 4 numbers, and by dragging the basis vectors i and j. These dialogs will allow the user to define new matrices to be used in expressions, and having multiple ways to do it will make it easier, and will aid learning.

Centre number: 123456

Another essential feature is animation. I want the user to be able to smoothly animate between matrices. I see two options for how this could work. If C is the matrix for the currently displayed transformation, and T is the matrix for the target transformation, then we could either animate from C to T or we could animate from C to TC. I would probably call these transitional and applicative animation respectively. Perhaps I'll give the user the option to choose which animation method they want to use. Either way, animation is used in most of the alternative solutions that I found, and it's a great way to build intuition, by allowing students to watch the transformation happen in real time. Compared to simply rendering the transformations, animating them would profoundly benefit learning, and since that's the main aim of the project, I think animation is a necessary part of the app.

Something that I thought was a big problem in every alternative solution I found was the fact that the user could only visualize a single matrix at once. I see this as a fatal flaw and I will allow the user to define 25 different matrices (all capital letters except I for the identity matrix) and use all of them in expressions. This will allow teachers to define multiple matrices and then just change the expression to demonstrate different concepts rather than redefine a new transformation every time. It will also make things easier for students as it will allow them to visualize compositions of different matrix transformations without having to do any computations themselves.

Additionally, being able to show information on the currently displayed matrix is an essential tool for learning. Rendering things like the determinant parallelogram and the invariant lines of the transformation will greatly assist with learning and building understanding, so I think that having the option to render these attributes of the currently displayed transformation is necessary for success.

1.5 Limitations

The main limitation in this app is likely to be drawing grid lines. Most transformations will be fine but in some cases, the app will be required to draw potentially thousands of grid lines on the canvas and this will probably cause noticeable lag, especially in the animations. I will have to artificially limit the number of grid lines that can be drawn on the screen. This won't look fantastic, because it means that the grid lines will only extend a certain distance from the origin, but it's an inherent limitation of computers. Perhaps if I was using a faster, compiled language like C++ rather than Python, this processing would happen faster and I could render more grid lines, but it's impossible to render all the grid lines and any implementation of this idea must limit them for performance.

An interesting limitation is that I don't think I'll implement panning. I suspect that I'll have to convert between coordinate systems and having the origin in the centre of the canvas will probably make the code much simpler. Also, linear transformations always leave the origin fixed, so always having it in the centre of the canvas seems thematically appropriate. Panning is certainly an option - the Desmos solution in §1.3.3 and GeoGebra solution in §1.3.4 both allow panning as a default part of Desmos and GeoGebra respectively, for example - but I don't think I'll implement it myself. I just don't think it's worth it.

I'm also not going to do any work with 3D linear transformations. 3D transformations are often harder to visualize and thus it would make sense to target them in an app like this, designed to help with learning and intuition, but 3D transformations are also harder to code. I would have to use a full graphics package rather than a simple widget, and I think it would be too much work for this project and I wouldn't be able to do it in the time frame. It's definitely a good idea, but I'm currently incapable of creating an app like that.

There are other limitations inherent to matrices. For instance, it's impossible to take an inverse of a singular matrix. There's nothing I can do about that without rewriting most of mathematics. Matrices can also only represent linear transformations. There's definitely a market for an app that could render any arbitrary transformation from $\mathbb{R}^2 \to \mathbb{R}^2$ - I know I'd want an app like that - but matrices can only represent linear transformations, so those are the only kind of transformations that I'll be looking at with this project.

Centre number: 123456

1.6 Hardware and software requirements

1.6.1 Hardware

Hardware requirements for the project are the same between the release and development environments and they're quite simple. I expect the app to require a processor with at least 1 GHz clock speed, \$BINARY_SIZE free disk space, and about 1 GB of available RAM. The processor and RAM requirements are needed by the Python runtime and mainly by Qt5 - the GUI library I'll be using. The \$BINARY_SIZE disk space is just for the executable binary that I'll compile for the public release. The code itself is less than 1 MB, but the compiled binary has to package all the dependencies and the entire CPython runtime to allow it to run on systems that don't have that, so the file size is much bigger.

I will also require that the user has a monitor that is at least 1920×1080 pixels in resolution. This isn't necessarily required, because the app will likely run in a smaller window, but a HD monitor is highly recommended. This allows the user to go fullscreen if they want to, and it gives them enough resolution to easily see everything in the app. A large, wall-mounted screen is also highly recommended for use in the classroom, although this is common among schools.

I will also require a keyboard with all standard Latin alphabet characters. This is because the matrices are defined as uppercase Latin letters. Any UK or US keyboard will suffice for this. The app will also require a mouse with at least one button. I don't intend to have right click do anything, so only the primary mouse button is required, although getting a single button mouse to actually work on modern computers is probably quite a challenge. A separate mouse is not strictly required - a laptop trackpad is equally sufficient.

1.6.2 Software

Software requirements differ slightly between release and development, although everything that the release environment requires is also required by the development environment. I will require a modern operating system - namely Windows 10 or later, macOS 10.9 'Mavericks' or later, or any modern Linux distro². Basically, it just requires an operating system that is compatible with Python 3.10 and Qt5, since I'll be using these in the project. Of course, Qt5 will need to be installed on the user's computer, although it's standard pretty much everywhere these days.

Python 3.10 won't actually be required for the end user, because I will be compiling the app into a stand-alone binary executable for release, and this binary will contain the required Python runtime and dependencies. However, if the user wishes to download and run the source code themself, then they will need Python 3.10 and the package dependencies: numpy, nptyping, and pyqt5. These can be automatically installed with the command python -m pip install -r requirements.txt from the root of the repository. numpy is a maths library that allows for fast matrix maths; nptyping is used by mypy for type-checking and isn't actually a runtime dependency but the imports in the typing module fail if it's not installed at runtime; and pyqt5 is a library that just allows interop between Python and Qt5, which is originally a C++ library.

¹Python 3.10 won't compile on any earlier versions of macOS[6]

²Specifying a Linux version is practically impossible. Python 3.10 isn't available in many package repositories, but will compile on any modern distro. Qt5 is available in many package repositories and can be compiled on any x86 or x86_64 generic Linux machine with gcc version 5 or later[7]

In the development environment, I use PyCharm for actually writing my code, and I use a virtual environment to isolate my project dependencies. There are also some development dependencies listed in the file dev_requirements.txt. They are: mypy, pyqt5-stubs, flake8, pycodestyle, pydocstyle, and pytest. mypy is a static type checker³; pyqt5-stubs is a collection of type annotations for the PyQt5 API for mypy to use; flake8, pycodestyle, and pydocstyle are all linters; and pytest is a unit testing framework. I use these libraries to make sure my code is good quality and actually working properly during development.

1.7 Success criteria

The main aim of the app is to help teach students about linear transformations. As such, the primary measure of success will be letting teachers get to grips with the app and then asking if they would use it in the classroom or recommend it to students to use at home.

Additionally, the app must fulfil some basic requirements:

- 1. It must allow the user to define multiple matrices in at least two different ways (numerically and visually)
- 2. It must be able to validate arbitrary matrix expressions
- 3. It must be able to render any valid matrix expression
- 4. It must be able to animate any valid matrix expression
- 5. It must be able to display information about the currently rendered transformation (determinant, eigenlines, etc.)
- 6. It must be able to save and load sessions (defined matrices, display settings, etc.)
- 7. It must allow the user to define and transform arbitrary polygons

Defining multiple matrices is a feature that I thought was lacking from every other solution I researched, and I think it would make the app much easier to use, so I think it's necessary for success. Validating matrix expressions is necessary because if the user tries to render an expression that doesn't make sense, has an undefined matrix, or contains the inverse of a singular matrix, then we have to disallow that or else the app will crash.

Visualizing matrix expressions as linear transformations is the core part of the app, so basic rendering of them is definitely a requirement for success. Animating these expressions is also a pretty crucial part of the app, so I would consider this necessary for success. Displaying the information of a matrix transformation is also very useful for building understanding, so I would consider this needed to succeed.

Saving and loading isn't strictly necessary for success, but it is a standard part of many apps, so will likely be expected by users, and it will benefit the app by allowing teachers to plan lessons in advance and save the matrices they've defined for that lesson to be loaded later.

Transforming polygons is the lowest priority item on this list and will likely be implemented last, but it would definitely benefit learning. I wouldn't consider it necessary for success, but it would be very good to include, and it's certainly a feature that I want to have.

If the majority of teachers would use and/or recommend the app and it meets all of these points, then I will consider the app as a whole to be a success.

 $^{^{3}}$ Python has weak, dynamic typing with optional type annotations but mypy enforces these static type annotations

2 Design

Candidate name: D. Dyson

2.1 Problem decomposition

I have decomposed the problem of visualization as follows:

Defining matrices is key to visualization because we need to have matrices to actually visualize. This is a key part of the app, and the user will be able to define multiple separate matrices numerically and visually using the GUI.

Evaluating expressions is another key part of the app and can be further broken down into validating, parsing, and computing the value. Validating an expression simply consists of checking that it adheres to a set of syntax rules for matrix expressions, and that it only contains matrices which have already been defined. Parsing consists of breaking an expression down into tokens, which are then much easier to evaluate. Computing the expression with these tokens is then just a series of simple operations, which will produce a final matrix at the end.

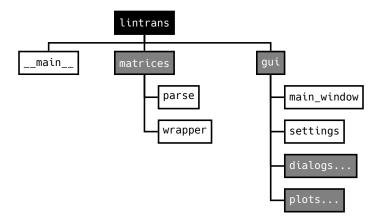

Rendering and animating will likely be the largest part in reality, but I've only decomposed it into simple blocks here. Evaluating positions involves evaluating the matrix expression that the user has input and using the columns of the resultant matrix to find the new positions of the basis vectors, and then extrapolating this for the rest of the plane. Rendering onto the widget is likely to be quite complicated and framework-dependent, so I've abstracted away the details for brevity here. Rendering will involve using the previously calculated values to render grid lines and vectors. Animating will probably be a for loop which just renders slightly different matrices onto the widget and sleeps momentarily between frames.

I have deliberately broken this problem down into parts that can be easily translated into modules in my eventual coded solution. This is simply to ease the design and development process, since now I already know my basic project structure. This problem could've been broken down into the parts that the user will directly interact with, but that would be less useful to me when actually starting development, since I would then have to decompose the problem differently to write the actual code.

2.2 Structure of the solution

2.2.1 The main project

I have decomposed my solution like so:

The lintrans node is simply the root of the whole project. __main__ is the Python way to make the project executable as python -m lintrans on the command line. For release, I will package it into a standalone binary executable.

matrices is the package that will allow the user to define, validate, parse, evaluate, and use matrices. The parse module will contain functions to validate matrix expressions - likely using regular expressions - and functions to parse matrix expressions. It will not know which matrices are defined, so validation will be naïve and evaluation will be elsewhere. The wrapper module will contain a MatrixWrapper class, which will hold a dictionary of matrix names and values. It is this class which will have aware validation - making sure that all matrices are actually defined - as well the ability to evaluate matrix expressions, in addition to its basic behaviour of setting and getting matrices. This matrices package will also have a create_rotation_matrix function that will generate a rotation matrix from an angle using the formula $\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$. It will be in the wrapper module since it's related to defining and manipulating matrices, but it will be exported and accessible as lintrans.matrices.create_rotation_matrix.

gui is the package that will contain all the frontend code for everything GUI-related. main_window is the module that will contain a LintransMainWindow class, which will act as the main window of the application and have an instance of MatrixWrapper to keep track of which matrices are defined and allow for evaluation of matrix expressions. It will also have methods for rendering and animating matrix expressions, which will be connected to buttons in the GUI. This module will also contain a simple main() function to instantiate and launch the application GUI.

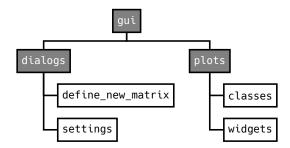

The settings module will contain a DisplaySettings dataclass⁴ that will represent the settings for visualizing transformations. The LintransMainWindow class will have an instance of this class and check against it when rendering things. The user will be able to open a dialog to change these display settings, which will update the main window's instance of this class.

The settings module will also have a GlobalSettings class, which will represent the global settings for the application, such as the logging level, where to save the logs, whether to ask the user if they want to be prompted with a tutorial whenever they open the app, etc. This class will have defaults for everything, but the constructor will try to read these settings from a config file if possible. This allows for persistent settings between sessions. This config file will be ~/.config/lintrans.conf on Unix-like systems, including macOS, and C:\Users\%USER%\AppData\Roaming\lintrans\config.txt on Windows. This difference is to remain consistent with operating system conventions⁵.

⁴This is the Python equivalent of a struct or record in other languages

 $^{^5\}mathrm{And}$ also to avoid confusing Windows users with a .conf file

2.2.2 The gui subpackages

The dialogs subpackage will contain modules with different dialog classes. It will have a define_new_matrices module, which will have a DefineDialog abstract superclass. It will also contain classes that inherit from this superclass and provide dialogs for defining new matrices visually, numerically, and as an expression in terms of other matrices. Additionally, this subpackage will contain a settings module, which will provide a SettingsDialog superclass and a DisplaySettingsDialog class, which will allow the user to configure the aforementioned display settings. It will also have a GlobalSettingsDialog class, which will similarly allow the user to configure the app's global settings through a dialog.

The plots subpackage will have a classes module and a widgets module. The classes module will have the abstract superclasses BackgroundPlot and VectorGridPlot. The former will provide helped methods to convert between coordinate systems and draw the background grid, while the latter will provide helper methods to draw transformations and their components. It will have point_i and point_j attributes and will provide methods to draw the transformed version of the grid, the vectors and their arrowheads, the eigenlines of the transformation, etc. These methods can then be called from the Qt5 paintEvent handler which will be declared abstract and must therefore be implemented by all subclasses.

The plots subpackage will also contain a widgets module, which will have the classes VisualizeTransformationWidget and DefineVisuallyWidget, both of which will inherit from VectorGridPlot. They will both implement their own paintEvent handler to actually draw the respective widgets, and DefineVisuallyWidget will also implement handlers for mouse events, allowing the user to drag around the basis vectors.

It's also worth noting here that I don't currently know how I'm going to implement the transformation of arbitrary polygons. It will likely consist of an attribute in VisualizeTransformationWidget which is a list of points, and these points can be dragged around with mouse event handlers and then the transformed versions can be rendered, but I'm not yet sure about how I'm going to implement it.

2.3 Algorithm design

This section will be completed later.

2.4 Usability features

My main concern in terms of usability is colour. In the 3blue1brown videos on linear algebra, red and green are used for the basis vectors, but these colours are often hard to distinguish in most common forms of colour blindness. The most common form is deuteranopia[8], which makes red and green look incredibly similar. I will use blue and red for my basis vectors. These colours are easy to distinguish for people with deuteranopia and protanopia - the two most common forms of colour blindness. Tritanopia makes it harder to distinguish blue and yellow, but my colour scheme is still be accessible for people with tritanopia, as red and blue are very distinct in this form of colour blindness.

I will probably use green for the eigenvectors and eigenlines, which will be hard to distinguish from the red basis vector for people with red-green colour blindness, but I think that the basis vectors and

eigenvectors/eigenlines will look physically different enough from each other that the colour shouldn't be too much of a problem. Additionally, I will use a tool called Color Oracle[9] to make sure that my app is accessible to people with different forms of colour blindness⁶.

Centre number: 123456

Another solution would be to have one default colour scheme, and allow the user to change the colour scheme to something more accessible for colour blind people, but I don't see the point in this. I think it's easier for colour blind people to just have the main colour scheme be accessible, and it's not really an inconvenience to non-colour blind people, so I think this is the best option.

The layout of my app will be self-consistent and follow standard conventions. I will have a menu bar at the top of the main window for actions like saving and loading, as well as accessing the tutorial (which will also be accessible by pressing F1 at any point) and documentation. The dialogs will always have the confirm button in the bottom right and the cancel button just to the left of that. They will also have the matrix name drop-down on the left. This consistency will make the app easier to learn and understand.

I will also have hotkeys for everything that can have hotkeys - buttons, checkboxes, etc. This makes my life easier, since I'm used to having hotkeys for everything, and thus makes the app faster to test because I don't need to click everything. This also makes things easier for other people like me, who prefer to stay at the keyboard and not use the mouse. Obviously a mouse will be required for things like dragging basis vectors and polygon vertices, but hotkeys will be available wherever possible to help people who don't like using the mouse or find it difficult.

2.5 Variables and validation

This project won't actually have many variables. The main ones will be instance attributes on the LintransMainWindow class. It will have a MatrixWrapper instance, a DisplaySettings instance, and a GlobalSettings instance. These will handle the matrices and various settings respectively. Having these as instance attributes allows them to be referenced from any method in the class, and Qt5 uses lots of slots (basically callback methods) and handlers, so it's good to be able to access the attributes I need right there rather than having to pass them around from method to method.

The MatrixWrapper class will have a dictionary of names and matrices. The names will be single letters 7 and the matrices will be of type MatrixType. This will be a custom type alias representing a 2×2 numpy array of floats. When setting the values for these matrices, I will have to manually check the types. This is because Python has weak typing, and if we got, say, an integer in place of a matrix, then operations would fail when trying to evaluate a matrix expression, and the program would crash. To prevent this, we have to validate the type of every matrix when it's set. I have chosen to use a dictionary here because it makes accessing a matrix by its name easier. We don't have to check against a list of letters and another list of matrices, we just index into the dictionary.

The settings dataclasses will have instance attributes for each setting. Most of these will be booleans, since they will be simple binary options like *Show determinant*, which will be represented with checkboxes in the GUI. The DisplaySettings dataclass will also have an attribute of type int representing the time in milliseconds to pause during animations.

The DefineDialog superclass have a MatrixWrapper instance attribute, which will be a parameter in the constructor. When LintransMainWindow spawns a definition dialog (which subclasses DefineDialog), it will pass in a copy of its own MatrixWrapper and connect the accepted signal for the dialog. The slot (method) that this signal is connected to will get called when the dialog is closed with the Confirm button⁸. This allows the dialog to mutate its own MatrixWrapper object and then the main window can copy that mutated version back into its own instance attribute when the user confirms the change. This reduces coupling and makes everything easier to reason about and debug, as well as reducing

 $^{^6}$ I actually had to clone a fork of this project[10] to get it working on Ubuntu 20.04 and adapt it slightly to create a working jar file

⁷I would make these char but Python only has a str type for strings

 $^{^8}$ Actually when the dialog calls .accept(). The Confirm button is actually connected to a method which first takes the info and updates the instance MatrixWrapper, and then calls .accept()

the number of bugs, since the classes will be independent of each other. In another language, I could pass a pointer to the wrapper and let the dialog mutate it directly, but this is potentially dangerous, and Python doesn't have pointers anyway.

Validation will also play a very big role in the application. The user will be able to enter matrix expressions and these must be validated. I will define a BNF schema and either write my own RegEx or use that BNF to programmatically generate a RegEx. Every matrix expression input will be checked against it. This is to ensure that the matrix wrapper can actually evaluate the expression. If we didn't validate the expression, then the parsing would fail and the program could crash. I've chosen to use a RegEx here rather than any other option because it's the simplest. Creating a RegEx can be difficult, especially for complicated patterns, but it's then easier to use it. Also, Python can compile a RegEx pattern, which makes it much faster to match against, so I will compile the pattern at initialization time and just compare expressions against that pre-compiled pattern, since we know it won't change at runtime.

Additionally, the buttons to render and animate the current matrix expression will only be enabled when the expression is valid. Textboxes in Qt5 emit a textChanged signal, which can be connected to a slot. This is just a method that gets called whenever the text in the textbox is changed, so I can use this method to validate the input and update the buttons accordingly. An empty string will count as invalid, so the buttons will be disabled when the box is empty.

I will also apply this matrix expression validation to the textbox in the dialog which allows the user to define a matrix as an expression involving other matrices, and I will validate the input in the numeric definition dialog to make sure that all the inputs are floats. Again, this is to prevent crashes, since a matrix with non-number values in it will likely crash the program.

2.6 Iterative test data

In unit testing, I will test the validation, parsing, and generation of rotation matrices from an angle. I will also unit test the utility functions for the GUI, like is_valid_float.

For the validation of matrix expressions, I will have data like the following:

Valid	Invalid
"A"	11 11
"AB"	"A^"
"-3.4A"	"rot()"
"A^2"	"A^{2"
"A^T"	"^12"
"A^{-1}"	"A^3.2"
"rot(45)"	"A^B"
"3A^{12}"	".A"
"2B^2+A^TC^{-1}"	"A"
"3.5A^45.6rot(19.2^T-B^-14.1C^5"	"AB"

This list is not exhaustive, mostly to save space and time, but the full unit testing code is included in appendix B.

The invalid expressions presented here have been chosen to be almost valid, but not quite. They are edge cases. I will also test blatantly invalid expressions like "This is a matrix expression" to make sure the validation works.

Here's an example of some test data for parsing:

Input	Expected
"A"	[[("", "A", "")]]
"AB"	[[("", "A", ""), ("", "B", "")]]
"2A+B^2"	[[("2", "A", ""), ("", "B", "2")]]
"3A^T2.4B^{-1}-C"	[[("3", "A", "T"), ("2.4", "B", "-1")], [("-1", "C", "")]]

The parsing output is pretty verbose and this table doesn't have enough space for most of the more complicated inputs, so here's a monster one:

which should parse to give:

Any invalid expression will also raise a parse error, so I will check every invalid input previously mentioned and make sure it raises the appropriate error.

Again, this section is brief to save space and time. All unit tests are included in appendix B.

2.7 Post-development test data

This section will be completed later.

3 Development

Please note, throughout this section, every code snippet will have two comments at the top. The first is the git commit hash that the snippet was taken from⁹. The second comment is the file name and line numbers. If the line numbers are omitted, then the snippet is the whole file. After a certain point, I introduced copyright comments at the top of every file. These are always omitted here.

Centre number: 123456

3.1 Matrices backend

3.1.1 MatrixWrapper class

The first real part of development was creating the MatrixWrapper class. It needs a simple instance dictionary to be created in the constructor, and it needs a way of accessing the matrices. I decided to use Python's __getitem__ and __setitem__ special methods[12] to allow indexing into a MatrixWrapper object like wrapper['M']. This simplifies using the class.

```
# 29ec1fedbf307e3b7ca731c4a381535fec899b0b
2
     # src/lintrans/matrices/wrapper.py
 4
     """A module containing a simple MatrixWrapper class to wrap matrices and context."""
5
     import numpy as np
8
     from lintrans.typing import MatrixType
10
     class MatrixWrapper:
11
12
         """A simple wrapper class to hold all possible matrices and allow access to them."""
13
14
         def __init__(self):
              """Initialise a MatrixWrapper object with a matrices dict."""
15
16
             self._matrices: dict[str, MatrixType | None] = {
17
                 'A': None, 'B': None, 'C': None, 'D': None,
                 'E': None, 'F': None, 'G': None, 'H': None,
18
19
                 'I': np.eye(2), # I is always defined as the identity matrix
20
                 'J': None, 'K': None, 'L': None, 'M': None,
21
                 'N': None, '0': None, 'P': None, 'Q': None,
22
                 'R': None, 'S': None, 'T': None, 'U': None,
                 'V': None, 'W': None, 'X': None, 'Y': None,
23
24
                 'Z': None
25
26
27
         def __getitem__(self, name: str) -> MatrixType | None:
28
                "Get the matrix with `name` from the dictionary.
29
30
             Raises:
31
                 KevError:
32
                     If there is no matrix with the given name
33
             return self._matrices[name]
34
35
36
         def __setitem__(self, name: str, new_matrix: MatrixType) -> None:
             """Set the value of matrix `name` with the new_matrix.
37
38
39
             Raises:
40
                 ValueError:
                     If `name` isn't a valid matrix name
41
42
43
             name = name.upper()
44
             if name == 'I' or name not in self._matrices:
45
46
                 raise NameError('Matrix name must be a capital letter and cannot be "I"')
47
48
             self._matrices[name] = new_matrix
```

 $^{^9\}mathrm{A}$ history of all commits can be found in the GitHub repository[11]

This code is very simple. The constructor (__init__) creates a dictionary of matrices which all start out as having no value, except the identity matrix I. The __getitem__ and __setitem__ methods allow the user to easily get and set matrices just like a dictionary, and __setitem__ will raise an error if the name is invalid. This is a very early prototype, so it doesn't validate the type of whatever the user is trying to assign it to yet. This validation will come later.

I could make this class subclass dict, since it's basically just a dictionary at this point, but I want to extend it with much more functionality later, so I chose to handle the dictionary stuff myself.

I then had to write unit tests for this class, and I chose to do all my unit tests using a framework called pytest.

```
# 29ec1fedbf307e3b7ca731c4a381535fec899b0b
     # tests/test_matrix_wrapper.py
     """Test the MatrixWrapper class."""
 4
6
     import numpy as np
     import pytest
     from lintrans.matrices import MatrixWrapper
9
10
     valid_matrix_names = 'ABCDEFGHJKLMNOPQRSTUVWXYZ'
11
     test_matrix = np.array([[1, 2], [4, 3]])
12
13
14
     @pytest.fixture
15
     def wrapper() -> MatrixWrapper:
16
         """Return a new MatrixWrapper object."""
17
         return MatrixWrapper()
18
19
20
     def test get matrix(wrapper) -> None:
21
         """Test MatrixWrapper.__getitem__()."""
22
         for name in valid matrix names:
23
             assert wrapper[name] is None
24
25
         assert (wrapper['I'] == np.array([[1, 0], [0, 1]])).all()
26
27
28
     def test_get_name_error(wrapper) -> None:
29
         """Test that MatrixWrapper.__getitem__() raises a KeyError if called with an invalid name."""
30
         with pytest.raises(KeyError):
            _ = wrapper['bad name']
31
             _ = wrapper['123456']
             _ = wrapper['Th15 Is an 1nV@l1D n@m3']
33
34
             _ = wrapper['abc']
35
36
37
     def test_set_matrix(wrapper) -> None:
38
         """Test MatrixWrapper.__setitem__()."""
39
         for name in valid_matrix_names:
40
             wrapper[name] = test_matrix
41
             assert (wrapper[name] == test_matrix).all()
42
43
44
     def test_set_identity_error(wrapper) -> None:
45
         """Test that MatrixWrapper.__setitem__() raises a NameError when trying to assign to I."""
46
         with pytest.raises(NameError):
47
             wrapper['I'] = test_matrix
48
49
50
     def test_set_name_error(wrapper) -> None:
51
         """Test that MatrixWrapper.__setitem__() raises a NameError when trying to assign to an invalid name."""
52
         with pytest.raises(NameError):
53
             wrapper['bad name'] = test_matrix
54
             wrapper['123456'] = test_matrix
             wrapper['Th15 Is an 1nV@l1D n@m3'] = test_matrix
55
             wrapper['abc'] = test_matrix
```

These tests are quite simple and just ensure that the expected behaviour works the way it should, and that the correct errors are raised when they should be. It verifies that matrices can be assigned, that every valid name works, and that the identity matrix I cannot be assigned to.

The function decorated with @pytest.fixture allows functions to use a parameter called wrapper and pytest will automatically call this function and pass it as that parameter. It just saves on code repetition.

3.1.2 Rudimentary parsing and evaluating

This first thing I did here was improve the __setitem__ and __getitem__ methods to validate input and easily get transposes and simple rotation matrices.

```
# f89fc9fd8d5917d07557fc50df3331123b55ad6b
2
     # src/lintrans/matrices/wrapper.pv:60-81
3
         def __setitem__(self, name: str, new_matrix: MatrixType) -> None:
             """Set the value of matrix `name` with the new_matrix.
5
 6
             :param str name: The name of the matrix to set the value of
8
             :param MatrixType new_matrix: The value of the new matrix
9
             :rtvpe: None
10
11
             :raises NameError: If the name isn't a valid matrix name or is 'I'
12
13
             if name not in self._matrices.keys():
14
                 raise NameError('Matrix name must be a single capital letter')
15
             if name == 'T':
16
17
                 raise NameError('Matrix name cannot be "I"')
18
19
             # All matrices must have float entries
20
             a = float(new_matrix[0][0])
21
             b = float(new_matrix[0][1])
22
             c = float(new_matrix[1][0])
23
             d = float(new_matrix[1][1])
24
             self._matrices[name] = np.array([[a, b], [c, d]])
```

In this method, I'm now casting all the values to floats. This is very simple validation, since this cast will raise **ValueError** if it fails to cast the value to a float. I should've declared :raises ValueError: in the docstring, but this was an oversight at the time.

```
# f89fc9fd8d5917d07557fc50df3331123b55ad6b
     # src/lintrans/matrices/wrapper.py:27-59
 3
         def __getitem__(self, name: str) -> Optional[MatrixType]:
             """Get the matrix with the given name.
5
 6
             If it is a simple name, it will just be fetched from the dictionary.
             If the name is followed with a 't', then we will return the transpose of the named matrix.
8
 9
             If the name is 'rot()', with a given angle in degrees, then we return a new rotation matrix with that angle.
10
11
             :param str name: The name of the matrix to get
12
             :returns: The value of the matrix (may be none)
13
             :rtype: Optional[MatrixType]
14
15
             :raises NameError: If there is no matrix with the given name
16
17
             # Return a new rotation matrix
18
             match = re.match(r'rot\((\d+)\))', name)
19
             if match is not None:
20
                 return create_rotation_matrix(float(match.group(1)))
21
22
             # Return the transpose of this matrix
```

```
23
             match = re.match(r'([A-Z])t', name)
24
             if match is not None:
25
                 matrix = self[match.group(1)]
26
27
                 if matrix is not None:
28
                     return matrix.T
29
30
                     return None
31
32
             if name not in self._matrices:
                 raise NameError(f'Unrecognised matrix name "{name}"')
33
34
35
             return self. matrices[name]
```

This <code>__getitem__</code> method now allows for easily accessing transposes and rotation matrices by checking input with regular expressions. This makes getting matrices easier and thus makes evaluating full expressions simpler.

The create_rotation_matrix() method is also defined in this file and just uses the $\begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}$ formula from before:

```
# f89fc9fd8d5917d07557fc50df3331123b55ad6b
     # src/lintrans/matrices/wrapper.py:158-168
     def create_rotation_matrix(angle: float) -> MatrixType:
         """Create a matrix representing a rotation by the given number of degrees anticlockwise.
6
         :param float angle: The number of degrees to rotate by
8
         :returns MatrixType: The resultant rotation matrix
9
10
         rad = np.deg2rad(angle)
11
         return np.array([
12
             [np.cos(rad), -1 * np.sin(rad)],
13
             [np.sin(rad), np.cos(rad)]
14
         1)
```

At this stage, I also implemented a simple parser and evaluator using regular expressions. It's not great and it's not very flexible, but it can evaluate simple expressions.

```
# f89fc9fd8d5917d07557fc50df3331123b55ad6b
     # src/lintrans/matrices/wrapper.py:83-155
 3
 4
         def parse_expression(self, expression: str) -> MatrixType:
              ""Parse a given expression and return the matrix for that expression.
 6
 7
             Expressions are written with standard LaTeX notation for exponents. All whitespace is ignored.
 8
9
             Here is documentation on syntax:
                A single matrix is written as 'A'.
10
                 Matrix A multiplied by matrix B is written as 'AB'
11
12
                Matrix A plus matrix B is written as 'A+B'
13
                Matrix A minus matrix B is written as 'A-B'
14
                 Matrix A squared is written as 'A^2'
15
                 Matrix A to the power of 10 is written as 'A^10' or 'A^{10}'
16
                 The inverse of matrix A is written as 'A^-1' or 'A^{-1}'
17
                 The transpose of matrix A is written as 'A^T' or 'At'
18
             :param str expression: The expression to be parsed
19
20
             :returns MatrixType: The matrix result of the expression
21
22
             :raises ValueError: If the expression is invalid, such as an empty string
23
             if expression == '':
24
25
                 raise ValueError('The expression cannot be an empty string')
26
27
             match = re.search(r'[^-+A-Z^{{}}rot()\d.]', expression)
28
             if match is not None:
```

```
29
                 raise ValueError(f'Invalid character "{match.group(0)}"')
30
31
             # Remove all whitespace in the expression
32
             expression = re.sub(r'\s', '', expression)
33
34
             # Wrap all exponents and transposition powers with {}
35
             expression = re.sub(r'(?<=\^)(-?\d+|T)(?=[^{}]|\$)', r'{\g<0>}', expression)
36
37
             # Replace all subtractions with additions, multiplied by -1
38
             expression = re.sub(r'(?<=.)-(?=[A-Z])', '+-1', expression)
39
             # Replace a possible leading minus sign with -1
40

44
             expression = expression.replace('^{T}', 't')
45
46
             # Split the expression into groups to be multiplied, and then we add those groups at the end
47
             # We also have to filter out the empty strings to reduce errors
             multiplication_groups = [x \text{ for } x \text{ in expression.split('+') if } x != '']
48
49
50
             # Start with the O matrix and add each group on
51
             matrix_sum: MatrixType = np.array([[0., 0.], [0., 0.]])
52
53
             for group in multiplication_groups:
54
                 # Generate a list of tuples, each representing a matrix
55
                 # These tuples are (the multiplier, the matrix (with optional
56
                 # 't' at the end to indicate a transpose), the exponent)
57
                 string_matrices: list[tuple[str, str, str]]
59
                 # The generate tuple is (multiplier, matrix, full exponent, stripped exponent)
60
                 # The full exponent contains ^{}, so we ignore it
                 # The multiplier and exponent might be '', so we have to set them to '1'
61
                 string_matrices = [(t[0] if t[0] != '' else '1', t[1], t[3] if t[3] != '' else '1')
62
63
                                   64
65
                 # This list is a list of tuple, where each tuple is (a float multiplier,
66
                 # the matrix (gotten from the wrapper's __getitem__()), the integer power)
67
                 matrices: list[tuple[float, MatrixType, int]]
68
                 matrices = [(float(t[0]), self[t[1]], int(t[2])) for t in string_matrices]
69
70
                 # Process the matrices and make actual MatrixType objects
71
                 processed\_matrices: \ list[MatrixType] = [t[0] * np.linalg.matrix\_power(t[1], \ t[2]) \ for \ t \ in \ matrices]
72
73
                 # Add this matrix product to the sum total
74
                 matrix_sum += reduce(lambda m, n: m @ n, processed_matrices)
75
76
             return matrix sum
```

I think the comments in the code speak for themselves, but we basically split the expression up into groups to be added, and then for each group, we multiply every matrix in that group to get its value, and then add all these values together at the end.

This code is objectively bad. At the time of writing, it's now quite old, so I can say that. This code has no real error handling, and line 48 introduces the glaring error that 'A++B' is now a valid expression because we disregard empty strings. Not to mention the fact that the method is called parse_expression but actually evaluates an expression. All these issues will be fixed in the future, but this was the first implementation of matrix evaluation, and it does the job decently well.

I then implemented several tests for this parsing.

These test lots of simple expressions, but don't test any more complicated expressions, nor do they test any validation, mostly because validation doesn't really exist at this point. 'A++B' is still a valid expression and is equivalent to 'A+B'.

3.1.3 Simple matrix expression validation

My next major step was to implement proper parsing, but I procrastinated for a while and first implemented proper validation.

```
# 39b918651f60bc72bc19d2018075b24a6fc3af17
    # src/lintrans/_parse/matrices.py:9-55
3
4
     def compile_valid_expression_pattern() -> Pattern[str]:
5
         """Compile the single regular expression that will match a valid matrix expression."""
6
        digit_no_zero = '[123456789]'
         digits = ' \d+'
         integer_no_zero = '-?' + digit_no_zero + '(' + digits + ')?'
8
9
         real_number = f'({integer_no_zero}(\\.{digits})?|-?0?\\.{digits})'
10
         index_content = f'({integer_no_zero}|T)'
11
         index = f'(\)^{{\{index\_content\}\}}}/^{index\_content\}}/
12
13
        matrix_identifier = f'([A-Z]|rot\\({real_number}\\))'
14
        matrix = '(' + real_number + '?' + matrix_identifier + index + '?)'
         expression = f'\{matrix\}+(()+|-)\{matrix\}+)*'
15
16
17
         return re.compile(expression)
18
19
20
     # This is an expensive pattern to compile, so we compile it when this module is initialized
21
    valid_expression_pattern = compile_valid_expression_pattern()
22
23
24
    def validate matrix expression(expression: str) -> bool:
25
         """Validate the given matrix expression.
26
27
         This function simply checks the expression against a BNF schema. It is not
28
        aware of which matrices are actually defined in a wrapper. For an aware
29
        version of this function, use the MatrixWrapper().is valid expression() method.
30
        Here is the schema for a valid expression given in a version of BNF:
31
32
                               ::= matrices { ( "+" | "-" ) matrices };
33
             expression
34
            matrices
                              ::= matrix { matrix };
                              ::= [ real_number ] matrix_identifier [ index ];
35
            matrix
36
            matrix_identifier ::= "A" .. "Z" | "rot(" real_number ")";
                              ::= "^{" index_content "}" | "^" index_content | "t";
37
            index
                              ::= integer_not_zero | "T";
38
            index_content
39
                              ::= "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
40
            digit_no_zero
41
                              ::= "0" | digit_no_zero;
            digit
42
            digits
                               ::= digit | digits digit;
            integer_not_zero ::= [ "-" ] digit_no_zero [ digits ];
43
44
                              ::= ( integer_not_zero [ "." digits ] | [ "-" ] [ "0" ] "." digits );
45
46
         :param str expression: The expression to be validated
47
         :returns bool: Whether the expression is valid according to the schema
48
49
        match = valid_expression_pattern.match(expression)
         return expression == match.group(0) if match is not None else False
```

Here, I'm using a BNF schema to programmatically generate a regular expression. I use a function to generate this pattern and assign it to a variable when the module is initialized. This is because the pattern compilation is expensive and it's more efficient to compile the pattern once and then just use it in the validate_matrix_expression() function.

I also created a method is_valid_expression() in MatrixWrapper, which just validates a given expression. It uses the aforementioned validate_matrix_expression() and also checks that every matrix referenced in the expression is defined in the wrapper.

```
# 39b918651f60bc72bc19d2018075b24a6fc3af17
# src/lintrans/matrices/wrapper.py:99-117

def is_valid_expression(self, expression: str) -> bool:
    """Check if the given expression is valid, using the context of the wrapper.

This method calls _parse.validate_matrix_expression(), but also ensures that all the matrices in the expression are defined in the wrapper.
```

```
10
             :param str expression: The expression to validate
11
             :returns bool: Whether the expression is valid according the schema
12
13
             # Get rid of the transposes to check all capital letters
14
             expression = re.sub(r'\^T', 't', expression)
             expression = re.sub(r'\^{T}', 't', expression)
15
             # Make sure all the referenced matrices are defined
17
18
             for matrix in {x for x in expression if re.match('[A-Z]', x)}:
19
                 if self[matrix] is None:
20
                     return False
21
22
             return parse.validate matrix expression(expression)
```

I then implemented some simple tests to make sure the function works with valid and invalid expressions.

```
# a0fb029f7da995803c24ee36e7e8078e5621f676
     # tests/_parse/test_parse_and_validate_expression.py

          for inp in inputs:
39
              assert validate_matrix_expression(inp) == output
```

Here, we test some valid data, some definitely invalid data, and some edge cases. At this stage, 'A--1B' was considered a valid expression. This was a quirk of the validator at the time, but I fixed it later. This should obviously be an invalid expression, especially since 'A--B' is considered invalid, but 'A--1B' is valid.

The <code>@pytest.mark.parametrize</code> decorator on line 35 means that <code>pytest</code> will run one test for valid inputs, and then another test for invalid inputs, and these will count as different tests. This makes it easier to see which tests failed and then debug the app.

3.1.4 Parsing matrix expressions

Parsing is quite an interesting problem and something I didn't feel able to tackle head-on, so I wrote the unit tests first. I had a basic idea of what I wanted the parser to return, but no real idea of how to implement that. My unit tests looked like this:

Centre number: 123456

```
# e9f7a81892278fe70684562052f330fb3a02bf9b
     # tests/_parse/test_parse_and_validate_expression.py:40-75
3
      expressions_and_parsed_expressions: list[tuple[str, MatrixParseList]] = [
5
          # Simple expressions
          " Sample Cxpressions

('A', [[('', 'A', '')]]),

('A^2', [[('', 'A', '2')]]),

('A^{2}', [[('', 'A', '2')]]),
6
8
           ('3A', [[('3', 'A', '')]]),
9
          ('1.4A^3', [[('1.4', 'A', '3')]]),
10
11
12
          # Multiplications
13
          ('4A^{3} 6B^2', [[('4', 'A', '3'), ('6', 'B', '2')]]),
          ('4.2A^{T} 6.1B^-1', [[('4.2', 'A', 'T'), ('6.1', 'B', '-1')]]),
14
          ('-1.2A^2 rot(45)^2', [[('-1.2', 'A', '2'), ('', 'rot(45)', '2')]]),
15
          ('3.2A^T 4.5B^{5} 9.6rot(121.3)', [[('3.2', 'A', 'T'), ('4.5', 'B', '5'), ('9.6', 'rot(121.3)', '')]]),
16
17
          ('-1.18A^{-2} 0.1B^{2} 9rot(34.6)^-1', [[('-1.18', 'A', '-2'), ('0.1', 'B', '2'), ('9', 'rot(34.6)', '-1')]]),
18
19
          # Additions
          "Additions"

('A + B', [[('', 'A', '')], [('', 'B', '')]]),

('A + B - C', [[('', 'A', '')], [('', 'B', '')], [('-1', 'C', '')]]),

('2A^3 + 8B^T - 3C^-1', [[('2', 'A', '3')], [('8', 'B', 'T')], [('-3', 'C', '-1')]]),
20
21
22
23
24
          # Additions with multiplication
          ('2.14A^{3} 4.5rot(14.5)^-1 + 8B^T - 3C^-1', [[('2.14', 'A', '3'), ('4.5', 'rot(14.5)', '-1')],
25
                                                                [('8', 'B', 'T')], [('-3', 'C', '-1')]]),
26
           ('2.14A^{3} 4.5rot(14.5)^-1 + 8.5B^T 5.97C^4 - 3.14D^{-1} 6.7E^T',
27
            [[('2.14', 'A', '3'), ('4.5', 'rot(14.5)', '-1')], [('8.5', 'B', 'T'), ('5.97', 'C', '4')],
28
             [('-3.14', 'D', '-1'), ('6.7', 'E', 'T')]]),
29
30
     1
31
32
33
     @pytest.mark.skip(reason='parse_matrix_expression() not implemented')
34
      def test_parse_matrix_expression() -> None:
           """Test the parse_matrix_expression() function."""
35
36
           for expression, parsed_expression in expressions_and_parsed_expressions:
37
               # Test it with and without whitespace
38
               \textbf{assert} \hspace{0.1cm} \texttt{parse\_matrix\_expression}(\texttt{expression}) \hspace{0.1cm} = \hspace{0.1cm} \texttt{parsed\_expression}
               assert parse_matrix_expression(expression.replace(' ', '')) == parsed_expression
```

I just had example inputs and what I expected as output. I also wanted the parser to ignore whitespace. The decorator on line 33 just skips the test because the parser wasn't implemented yet.

When implementing the parser, I first had to tighten up validation to remove anomalies like 'A--1B' being valid. I did this by factoring out the optional minus signs from being part of a number, to being optionally in front of a number. This eliminated this kind of repetition and made 'A--1B' invalid, as it should be.

```
# fd80d8d3b0e975e92dcc7c10f1f0f1276879f408
     # src/lintrans/_parse/matrices.py:32-45
     def compile valid expression pattern() -> Pattern[str]:
5
         """Compile the single regular expression that will match a valid matrix expression."""
 6
         digit_no_zero = '[123456789]'
         digits = ' \d+'
8
         integer_no_zero = digit_no_zero + '(' + digits + ')?'
9
         real_number = f'({integer_no_zero}(\\.{digits})?|0?\\.{digits})'
10
11
         index_content = f'(-?{integer_no_zero}|T)'
12
         index = f'(\)^{{\{index\_content\}}}/^{index\_content\}}/
13
         matrix_identifier = f'([A-Z]|rot\\(-?{real_number}\\))'
```

```
14  matrix = '(' + real_number + '?' + matrix_identifier + index + '?)'
15  expression = f'-?{matrix}+((\\+|-){matrix}+)*'
16
17  return re.compile(expression)
```

The code can be a bit hard to read with all the RegEx stuff, but the BNF illustrates these changes nicely.

Compare the old version:

```
# 39b918651f60bc72bc19d2018075b24a6fc3af17
    # src/lintrans/_parse/matrices.py:38-49
    expression
                     ::= matrices { ( "+" | "-" ) matrices };
5
    matrices
                      ::= matrix { matrix };
    matrix
                      ::= [ real_number ] matrix_identifier [ index ];
    matrix_identifier ::= "A" .. "Z" | "rot(" real_number ")";
                     ::= "^{" index_content "}" | "^" index_content | "t";
8
    index
     index_content
                    ::= integer_not_zero | "T";
10
    digit_no_zero ::= "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
11
12
    digit
                      ::= "0" | digit_no_zero;
                      ::= digit | digits digit;
13
    digits
    integer_not_zero ::= [ "-" ] digit_no_zero [ digits ];
14
15
    real_number ::= ( integer_not_zero [ "." digits ] | [ "-" ] [ "0" ] "." digits );
     to the new version:
    # fd80d8d3b0e975e92dcc7c10f1f0f1276879f408
2
    # src/lintrans/_parse/matrices.py:61-72
                      ::= [ "-" ] matrices { ( "+" | "-" ) matrices };
4
    expression
                     ::= matrix { matrix };
6
                      ::= [ real_number ] matrix_identifier [ index ];
    matrix
    \label{eq:matrix_identifier} \mbox{\tt matrix\_identifier} ::= \mbox{\tt "A" .. "Z" | "rot(" [ "-" ] real\_number ")"};
                     ::= "^{" index_content "}" | "^" index_content | "t";
9
     index_content ::= [ "-" ] integer_not_zero | "T";
10
11
    digit_no_zero ::= "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9";
                      ::= "0" | digit_no_zero;
12
    digit
13
    digits
                      ::= digit | digits digit;
14
    integer_not_zero ::= digit_no_zero [ digits ];
15
    real number
                     ::= ( integer_not_zero [ "." digits ] | [ "0" ] "." digits );
```

Then once I'd fixed the validation, I could implement the parser itself.

```
# fd80d8d3b0e975e92dcc7c10f1f0f1276879f408
     # src/lintrans/_parse/matrices.py:86-128
 4
     def parse_matrix_expression(expression: str) -> MatrixParseList:
         """Parse the matrix expression and return a list of results.
 6
         The return value is a list of results. This results list contains lists of tuples.
8
         The top list is the expressions that should be added together, and each sublist
9
         is expressions that should be multiplied together. These expressions to be
         multiplied are tuples, where each tuple is (multiplier, matrix identifier, index).
11
         The multiplier can be any real number, the matrix identifier is either a named
12
         matrix or a new rotation matrix declared with 'rot()', and the index is an
         integer or 'T' for transpose.
13
14
15
         :param str expression: The expression to be parsed
16
         :returns MatrixParseTuple: A list of results
17
         # Remove all whitespace
18
19
         expression = re.sub(r'\s', '', expression)
20
```

```
21
        # Check if it's valid
22
        if not validate_matrix_expression(expression):
23
            raise MatrixParseError('Invalid expression')
24
25
        # Wrap all exponents and transposition powers with {}
26
        expression = re.sub(r'(?<=^{()}(-?\d+|T)(?=[^{]}|$)', r'{\g<0>}', expression)
27
28
        # Remove any standalone minuses
29
        expression = re.sub(r'-(?=[A-Z])', '-1', expression)
30
31
        # Replace subtractions with additions
32
        expression = re.sub(r'-(?=\d+\.?\d*([A-Z]|rot))', '+-', expression)
33
        # Get rid of a potential leading + introduced by the last step
34
35
        expression = re.sub(r'^+, '', expression)
36
37
        return [
38
            Γ
               # The tuple returned by re.findall is (multiplier, matrix identifier, full index, stripped index),
39
40
                # so we have to remove the full index, which contains the {}
41
               (t[0], t[1], t[3])
                42
43
44
            # We just split the expression by '+' to have separate groups
45
            for group in expression.split('+')
```

It works similarly to the old MatrixWrapper.parse_expression() method in §3.1.2 but with a powerful list comprehension at the end. It splits the expression up into groups and then uses some RegEx magic to find all the matrices in these groups as a tuple.

This method passes all the unit tests, as expected.

My next step was then to rewrite the evaluation to use this new parser, like so (method name and docstring removed):

```
# a453774bcdf824676461f9b9b441d7b94969ea55
     # src/lintrans/matrices/wrapper.py:168-191
3
 4
             if not self.is_valid_expression(expression):
 5
                 raise ValueError('The expression is invalid')
 6
             parsed_result = _parse.parse_matrix_expression(expression)
 8
             final_groups: list[list[MatrixType]] = []
9
10
             for group in parsed_result:
11
                 f_group: list[MatrixType] = []
12
13
                 for matrix in group:
                     if matrix[2] == 'T':
14
15
                         m = self[matrix[1]]
16
                         assert m is not None
17
                         matrix_value = m.T
18
19
                         matrix_value = np.linalg.matrix_power(self[matrix[1]],
20
                                                                1 if (index := matrix[2]) == '' else int(index))
21
                     matrix_value *= 1 if (multiplier := matrix[0]) == '' else float(multiplier)
22
23
                     f_group.append(matrix_value)
24
25
                 final_groups.append(f_group)
27
             return reduce(add, [reduce(matmul, group) for group in final_groups])
```

Here, we go through the list of tuples and evaluate the matrix represented by each tuple, putting this together in a list as we go. Then at the end, we simply reduce the sublists and then reduce these new matrices using a list comprehension in the reduce() call using add and matmul from the operator library. It's written in a functional programming style, and it passes all the previous tests.

3.2 GUI

3.2.1 First basic GUI

After implementing most of the backend and testing it thoroughly, I wanted to start work on the actual GUI. The discrepancy in all the GUI code between snake_case and camelCase is because Qt5 was originally a C++ framework that was adapted into PyQt5 for Python.

Centre number: 123456

```
# 93ce763f7b993439fc0da89fad39456d8cc4b52c
     # src/lintrans/qui/main window.pv
3
 4
     """The module to provide the main window as a QMainWindow object."""
5
6
     import sys
8
     from PyQt5 import QtCore, QtGui, QtWidgets
9
     from PyQt5.QtWidgets import QApplication, QHBoxLayout, QMainWindow, QVBoxLayout
10
11
     from lintrans.matrices import MatrixWrapper
12
13
14
     class LintransMainWindow(QMainWindow):

164
          main()
```

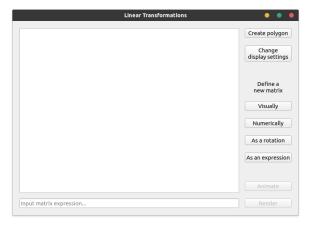

Figure 5: The first version of the GUI

A lot of the methods here don't have implementations yet, but they will. This version is just a very early prototype to get a rough draft of the GUI.

I create the widgets and layouts in the constructor as well as configuring all of them. The most important non-constructor method is update_render_buttons. It gets called whenever the text in text_input_expression is changed. This happens because we connect it to the textChanged signal on line 35.

The big white box here will eventually be replaced with an actual viewport. This is just a prototype.

3.2.2 Numerical definition dialog

14

My next major addition was a dialog that would allow the user to define a matrix numerically.

```
# cedbd3ed126a1183f197c27adf6dabb4e5d301c7
# src/lintrans/gui/dialogs/define_new_matrix.py

"""The module to provide dialogs for defining new matrices."""

from numpy import array
from PyQt5 import QtGui, QtWidgets
from PyQt5.QtWidgets import QDialog, QGridLayout, QHBoxLayout, QVBoxLayout

from lintrans.matrices import MatrixWrapper

ALPHABET_NO_I = 'ABCDEFGHJKLMNOPQRSTUVWXYZ'
```

```
15
         def is_float(string: str) -> bool:
                 """Check if a string is a float."""
16
17
                try:
18
                        float(string)
19
                       return True
20
                except ValueError:
21
                       return False
22
23
24
         class DefineNumericallyDialog(QDialog):
25

```

144

self.close()

Figure 6: The first version of the numerical definition dialog

When I add more definition dialogs, I will factor out a superclass, but this is just a prototype to make sure it all works as intended.

Hopefully the methods are relatively self explanatory, but they're just utility methods to update the GUI when things are changed. We connect the QLineEdit widgets to the update_confirm_button slot to make sure the confirm button is always up to date.

The confirm_matrix method just updates the in-

stance's matrix wrapper with the new matrix. We pass a reference to the LintransMainWindow instance's matrix wrapper when we open the dialog, so we're just updating the referenced object directly.

In the LintransMainWindow class, we're just connecting a lambda slot to the button so that it opens the dialog, as seen here:

```
1  # cedbd3ed126a1183f197c27adf6dabb4e5d301c7
2  # src/lintrans/gui/main_window.py:66-68
3
4  self.button_define_numerically.clicked.connect(
5  lambda: DefineNumericallyDialog(self.matrix_wrapper, self).exec()
6  )
```

46
         Let ``C`` be the matrix representing the currently displayed transformation, and let ``T`` be the target matrix.
         Transitional animation means that we animate directly from ``C`` from ``T``, and applicative animation means that we animate from ``C`` to ``TC``, so we apply ``T`` to ``C``.

     matrix_identifier, index)`` where all of them are strings. These matrix-representing tuples are
29
30
     contained in lists which represent multiplication groups. Every matrix in the group should be
```

```
multiplied together, in order. These multiplication group lists are contained by a top level list,
32
     which is this type. Once these multiplication group lists have been evaluated, they should be summed.
33
34
     In the tuples, the multiplier is a string representing a real number, the matrix identifier
35
     is a capital letter or ``rot(x)`` where x is a real number angle, and the index is a string
     representing an integer, or it's the letter ``T`` for transpose.
